Quantum Key Distribution (QKD) [Bennett, Brassard 84]

- Security based on **No-Cloning Theorem** and **Uncertainty Principle**
- Error rate ⚡ statistical monitoring → Bound on information leaked to Eve

QKD provides crypto advantage over computational key establishment techniques:

- no assumptions on Eve's computing power
- future-proof security

The black paper of quantum cryptography: real implementation problems

Valerio Scarani, Christian Kurtsiefer

« This leads us to guess that **the field**, similar to non-quantum modern cryptography, **is going to split in two directions:**

those who pursue practical devices may have to moderate their security claims

Practical QC

those who pursue ultimate security may have to suspend their claims of usefulness. »

Abstract QC

Why not take the fork i.e. Acknowledge that Abstract QC \neq Practical QC ?

ITS Security deeply Rooted in QCrypto Program:

“Conventional cryptosystems such as ENIGMA, DES, or even RSA, are based on a mixture of guess work and mathematics. Information theory shows that traditional secret-key cryptosystem cannot be totally secure unless the key, used once only, is at least as long as the cleartext. On the other hand, the theory of computational complexity is not yet well enough understood to prove the computational security of public- key cryptosystems. In this paper we use a radically different foundation for cryptography, viz. the uncertainty principle of quantum physics. In conventional information theory and cryptography it is taken for granted that digital communications in principle can always be passively monitored or copied, even by someone ignorant of their meaning.”

Charles H. Bennett et Gilles Brassard (1984)

➤ **High symbolic Cost:** (for abstract QC)

Abstract Q Crypto may not directly apply to Real Systems.

➔ *Security Proofs cannot guarantee Absolute Security ?*

➤ **High Ontological Cost:** (for practical QC)

Performance/Cost
(Practicality)

Practical Quantum Cryptography Dilemma:

Obvious next steps towards practicality have negative side-effects

- Improvements of performance / cost : **technology upgrade, simplification** generally decrease security (at least at short term)
- Increasing implementation security: **countermeasures, security certification** tend to increase cost and decrease performances

Way Forward:

QCT Security Model

(quantum computational time-lock)

1) Short-term secure encryption

2) Time-limited quantum storage

$$\|\mathcal{N}_t(\rho) - \frac{I_d}{d}\| \leq O\left(\frac{1}{d}\right) \quad \forall t > t_{coh}$$

❑ Top secret (AES Encryption) $t \approx 10^8 \text{ sec}$

❑ Coherence time $\approx O(1) \text{ sec}$

$$t_{coh} < t_{comp}$$

Very likely to hold (in the future too)
