# What Is Network Coding?

Figure: The butterfly network

- Source node  $s$
- Two destination nodes  $t_1$  and  $t_2$
- Two bits per sec,  $x$  and  $y$ , are available at  $s$
- All links are of capacity 1 bit/s

## Problem

Multicast the information available at the source to all the destinations

# Classical Approach

- Route the information along trees in the network
- we want to maximize the multicast rate to each destination
- $\Rightarrow$  Problem of Packing Steiner trees in graphs. **NP-hard!**
- average rate here 1.5 bits/s

Figure: Routing (Steiner trees)

# Network Coding

- Network coding

- ▶ Is an extension of routing
- ▶ Allows "mixing" of packets at intermediate nodes
- ▶ Achieves higher throughput

Figure: Network coding solution

# Linear Network Codes

## Definition (Linear Network Code)

It is the collection of all the local encoding vectors for all the edges of a network.

- $s_1, s_2, s_3 \in GF(q)$
- $Y(e) = am_1 + bm_2$
- $(a, b)$  is the **local encoding vector** of edge  $e$
- $Y(e) = \alpha s_1 + \beta s_2 + \gamma s_3$
- $(\alpha, \beta, \gamma)$  **global encoding vector** of edge  $e$

Figure: Linear Network Codes

# Wiretapped Butterfly

- Assume the existence of a **wiretapper**
  - ▶ who can intercept the packets on any single edge of his choice
- How can we send data **securely** to both destinations?
  - ▶ i.e. without letting the wiretapper gain any information about the data

Figure: The butterfly network

# Secure Butterfly

Figure: Secure Solution

- $x, r \in GF(3)$
- $r$  randomly generated
- One symbol ( $x$ ) is sent securely to  $t_1$  and  $t_2$
- The data is "hidden" from the wiretapper
- Note the need to use a field with a size larger than 2

# The Wiretap Network Model

- Network represented by an acyclic directed graph  $G(V, E)$ ;  $|E| = N$
- Source  $s$  where  $h$  packets  $S = (s_1, \dots, s_h)^T \in GF^h(q)$  are available
- $k$  destination nodes  $t_1, \dots, t_k$  that demand **all** the packets
- Min-cut between  $s$  and any  $t_i$  is  $n$

Figure: multicast network  
 $(h, k) = (3, 3)$ .

# Model - The Wiretapper

## The **wiretapper**

- Can access the packets carried by any  $\mu < n$  edges of his choice
- Knows the network code used
- Knows any keys shared between the  $s$  and the  $t_i$ 's. (Key Cryptography is not possible here)

# Problem Definition

## Definition (Secure Multicast Problem)

Given a wiretap network, find, if possible, a linear network code that will

- deliver  $h$  packets to all the destinations
- achieve **perfect secrecy** by hiding all the information data from the wiretapper

# Classical Security

## Classical security

- Based on the conjectured hardness of some known problems such as *factoring* large integers
- Assume a computationally bounded adversary

## Categories

- Symmetric Key Cryptography: DES, AES, hash functions
- Public Key Cryptography: RSA algorithm

# Information-Theoretic Security

## Information-theoretical security

- Based on concepts from information theory such as *entropy*
- No assumption on the strength of the adversary

*Shannon, C. E., "A Communication Theory of Secrecy Systems," 1949, Bell Labs*

# Network Security

- Let  $W$  the set of  $\mu$  edges observed by the wiretapper
- $Z_W = (z_1, \dots, z_\mu)$  the observed packets
- $H(S|Z_W)$  = how much information we are hiding from the wiretapper when he observes the edges in  $W$
- $H(S)$  = how much information we are sending to the destinations

## Definition (Security Condition)

We say that the network is secure iff

$$H(S|Z_W) = H(S) \quad \forall W \subset E$$

# Network Security

- Let  $W$  the set of  $\mu$  edges observed by the wiretapper
- $Z_W = (z_1, \dots, z_\mu)$  the observed packets
- $H(S|Z_W)$  = how much information we are hiding from the wiretapper when he observes the edges in  $W$
- $H(S)$  = how much information we are sending to the destinations

## Definition (Security Condition)

We say that the network is secure iff

$$H(S|Z_W) = H(S) \quad \forall W \subset E$$

# Network Security

## Definition (Security Condition)

We say that the network is secure iff

$$H(S|Z_w) = H(S) \quad \forall W \subset E$$

# Related Work (1)

- Cai & Yeung were first to define this problem (2002).
- They constructed multicast codes that can securely send  $h = n - \mu$  packets  $(S = (s_1, \dots, s_h)^T)$  to all the destinations
  - ① multicast information packets  $(S = (s_1, \dots, s_h)^T)$  to all the destinations
  - ② at rate  $= \frac{h}{n}$  (i.e. by adding  $\mu = n - h$  redundant packets)
  - ③ achieve perfect secrecy

# Secure Multicast Scheme

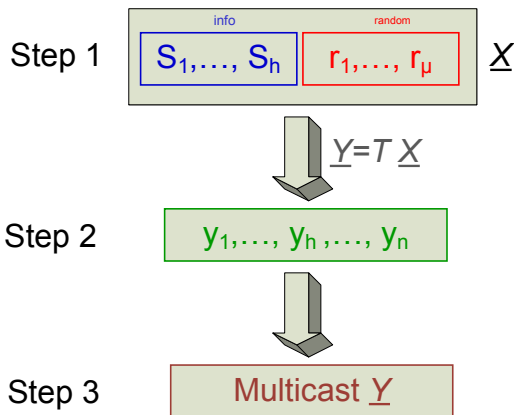

Figure: Secure Solution

# Related Work

## Theorem (1)

*Let  $Y = TX$ . The resulting code is secure iff any set of vectors consisting of*

- 1 *at most  $\mu$  l.i. global encoding vectors*
- 2 *vectors from the first  $h$  rows of  $T^{-1}$*

*is linearly independent. [Feldman et al. 2004, Cai&Yeung 2002]*

## Related Work (2)

### Theorem (2)

*Secure linear network codes ( $h = n - \mu$ ) exist over  $GF(q)$ ,  $\forall q > \binom{N}{\mu}$*

- *$N$  is the number of edges in the Network*
- *$\mu$  is the number of edges that the wiretapper can observe*

*[Cai&Yeung 2002]*

# Contributions

- We look at the wiretap multicast network as an *generalization* of **the wiretap channel of type II** (WTCII) [Ozarow & Wyner 1984]
- We study a secure multicast scheme using **coset codes**, originally proposed for the WTCII
- We show that this scheme is *equivalent* to the previously described one. Nevertheless it allows to recover very easily Theorem 1 (and therefore Theorem 2)
- We also improve on the bound on the field size, by showing that secure multicast codes exist over  $GF(q)$ ,  $\forall q \geq \binom{h^3 k^2 + \delta}{\mu - 1} + k$ ;  $\delta$  is the source node degree

  - Review
  - Coset Codes for the Wiretap Network
- 3 Code Alphabet
  - Bound on the Field Size
- 4 Conclusion

## WTCII- Ozarow &amp; Wyner 84

- A transmitter can send  $n$  symbols  $X = (x_1, \dots, x_n)$  to a receiver through a **noiseless channel**
- A wiretapper can observe  $Z_W = (z_1, \dots, z_\mu)$ , a subset  $W$  of his choice of size  $\mu < n$  of the transmitted symbols
- The transmitter wants to communicate  $h$  symbols  $S = (s_1, \dots, s_h)$  **securely** to the receiver
- The problem is to find an encoding of  $S$  into  $X$  that maximizes  $\Delta = \min_W H(S/Z_W)$

# Example of a Code for the WTCII

Set of all possible transmitted symbols

- $n = 2; h = \mu = 1$
- Code
  - ▶  $s = 0 \longrightarrow A_0 = \{00, 11\}$
  - ▶  $s = 1 \longrightarrow A_1 = \{01, 10\}$
- If the input to the encoder is  $s$ , then the output is a random element of  $A_s$
- It can be shown that this code achieves **perfect secrecy**, i.e.  $\Delta = 1$

# Codes for the WTCII

- ① Partition
- ② Toss a die
- ③ Send

Figure: Partition  $\Sigma^n$

# Coset Codes

**Figure:** Partition by cosets  
 $GF(q)^n / C$

- $\Sigma = GF(q)$
- Let  $C$  be  $(n, n - h)$   $q$ -ary code (i.e. a linear subspace of  $\dim n - h$ )
- The partitions  $A_i$ 's are the cosets of  $C$  ( $x + C$ )
- Let  $H$  be the  $n \times h$  parity check matrix of  $C$
- Choose the subset  $A_S$  associated with  $S \in GF^h(q)$  to be

$$A_S = \{X \in GF^n(q); HX = S\}$$

# Example Revisited

Set of all possible transmitted symbols

The previous code is a coset code where  $H = [1 \ 1]$

# Performance of Coset Codes

## Theorem (Ozarow & Wyner)

Consider a coset code of parity check matrix  $H$  of columns  $h_i$  ( $1 \leq i \leq n$ ). Let  $W \subseteq \{1, 2, \dots, n\}$ . Then,

$$\Delta = \min_{|W|=n-\mu} \text{rank}\{h_j; j \in W\}$$

# Coset Codes for the Wiretap Network

Figure: Wiretap network equivalent to the WTCII

- WTCII can be regarded as an instance of the wiretap network
- Use coset codes to achieve security for the wiretap multicast network:
  - ▶ Encode  $S = (s_1, \dots, s_h)^T$  into  $Y = (y_1, \dots, y_n)^T$  using a coset code of parity check matrix  $H$
  - ▶ Use a network code to multicast  $Y$  to all the destinations

# Questions

- 1 How is the coset code scheme different than the one proposed by Cai & Yeung?
- 2 How should the parity check matrix  $H$  be chosen to ensure the security condition?

# Equivalence

C&Y secure network code ( $\mu = n - h$ )

- 1 Randomly generate  $R = (r_1, \dots, r_{n-h})^T$
- 2  $Y = T * (s_1, \dots, s_h, r_1, \dots, r_{n-h})^T$
- 3 Use a network code to multicast  $Y = (y_1, \dots, y_n)^T$

## Lemma

*C&Y secure network code is equivalent to a coset code of parity check matrix  $H = T^*$ , where  $T^*$  is formed by taking the first  $h$  rows of  $T^{-1}$*

# The Parity Check Matrix

- Let  $W \subset E$  be the set of the  $\mu = n - h$  wiretapped edges
- $Z_W$  the packets observed on these edges
- WLOG, the global encoding vectors of these edges are linearly independent
- $C_W$  an  $(n - h) \times n$  matrix formed by these vectors

## Theorem (III)

*A coset code with a parity check matrix  $H$  satisfies the security condition iff  $M_W = \begin{bmatrix} H \\ C_W \end{bmatrix}$  is invertible  $\forall W$*

Theorem 3 is equivalent to Theorem 1.

# The Parity Check Matrix

- Let  $W \subset E$  be the set of the  $\mu = n - h$  wiretapped edges
- $Z_W$  the packets observed on these edges
- WLOG, the global encoding vectors of these edges are linearly independent
- $C_W$  an  $(n - h) \times n$  matrix formed by these vectors

## Theorem (III)

*A coset code with a parity check matrix  $H$  satisfies the security condition iff  $M_W = \begin{bmatrix} H \\ C_W \end{bmatrix}$  is invertible  $\forall W$*

Theorem 3 is equivalent to Theorem 1.

# Simple Proof

- Remember

- ▶ Data vector  $S = (s_1, \dots, s_h)$
- ▶ Transmitted vector  $Y = (y_1, \dots, y_n)$  chosen randomly among the solutions of  $HY = S$
- ▶  $Z_w = (z_1, \dots, z_{n-h})$  wiretapped data;  $Z_w = C_w Y$

- $H(Y|S, Z_w) = H(S|Y, Z_w) + H(Y|Z_w) - H(S|Z_w)$

- $H(S|Y, Z_w) = 0$  cosets are disjoint

- $H(S|Z_w) = H(S) = k$  security condition

- $H(Y|Z_w) = n - \text{rank}(C_w) = n - (n - h) = h$

- $\Rightarrow H(Y|S, Z_w) = 0$  and the system  $HY = S$  &  $C_w Y = Z_w$  has a unique solution

# Simple Proof

- Remember

- ▶ Data vector  $S = (s_1, \dots, s_h)$
- ▶ Transmitted vector  $Y = (y_1, \dots, y_n)$  chosen randomly among the solutions of  $HY = S$
- ▶  $Z_w = (z_1, \dots, z_{n-h})$  wiretapped data;  $Z_w = C_w Y$

- $H(Y|S, Z_w) = H(S|Y, Z_w) + H(Y|Z_w) - H(S|Z_w)$

- $H(S|Y, Z_w) = 0$  cosets are disjoint

- $H(S|Z_w) = H(S) = k$  security condition

- $H(Y|Z_w) = n - \text{rank}(C_w) = n - (n - h) = h$

- $\Rightarrow H(Y|S, Z_w) = 0$  and the system  $HY = S$  &  $C_w Y = Z_w$  has a unique solution

# Simple Proof

  - The Wiretap Multicast Network
- 2 The Wiretap Channel of type II
  - Review
  - Coset Codes for the Wiretap Network
- 3 Code Alphabet
  - Bound on the Field Size
- 4 Conclusion

# A Different Approach

- Previous approach
  - ▶ Use a secure code on top of an already designed network code to achieve security
- New approach
  - ▶ Incorporate the security condition in the algorithm that constructs the network code
- We gain better bound on the field size

# Jaggi's Algorithm

Sketch of Jaggi's et al. algorithm for finding (not necessarily secure) network codes

Figure: Flows

- 1 Find  $k$  (# of destinations) **flows**  $(F_1, \dots, F_k)$  each of  $h$  **disjoint paths**
- 2 Visit the network edges in **topological order**
- 3 Let  $B_{F_i}$  an  $h \times h$  **matrix** formed by the  $h$  global encoding vectors of the last processed edges of flow  $F_i$
- 4 Find the encoding vector for the currently visited edge such that all the  $k$  **matrices**  $B_{F_i}$  are invertible

# Bound on the Field Size

## Theorem

*There is always a linear multicast network code over  $GF(q)$ ,  $\forall q \geq k$  [Jaggi et al. 2003]*

- The proof is by construction and follows from the correctness of Jaggi's algorithm
- A field of size  $q \geq k$  is sufficient for keeping the  $k$  matrices  $B_{F_i}$  invertible

## Theorem (I)

*Secure linear network codes exist over  $GF(q)$ ,  $\forall q > \binom{N}{\mu}$ . [Cai & Yeung 2002]*

# Bound on the Field Size

## Theorem

*There is always a linear multicast network code over  $GF(q)$ ,  $\forall q \geq k$  [Jaggi et al. 2003]*

- The proof is by construction and follows from the correctness of Jaggi's algorithm
- A field of size  $q \geq k$  is sufficient for keeping the  $k$  matrices  $B_{F_i}$  invertible

## Theorem (I)

*Secure linear network codes exist over  $GF(q)$ ,  $\forall q > \binom{N}{\mu}$ . [Cai & Yeung 2002]*

# Special Case

- Assume the wiretapper can intercept only one edge ( $\mu = 1$ )
- Coset code of parity check matrix  $H$  is to be used
- We modify Jaggi's algorithm so it outputs a secure network code in the following way
  - ▶ When looping over the edges of the network, choose the global encoding vector  $U(e)$  such that
    - ① The  $k$  matrices  $B_{F_i}$  invertible
    - ② The matrix  $\begin{bmatrix} H \\ U(e) \end{bmatrix}$  is invertible (Theorem 3)
- $k + 1$  constraints  $\Rightarrow$  A field of size  $q \geq k + 1$  is sufficient
- Compare to the  $\binom{N}{1} = N$  bound ( $N$  is the number of edges in the network)

# Bound for the General Case

## Theorem

*Secure linear network codes for a wiretap multicast network exist over  $GF(q)$ ,  $\forall q \geq \binom{N-1}{\mu-1} + k$ .*

## Theorem

*Secure linear network codes for a wiretap multicast network exist over  $GF(q)$ ,  $\forall q \geq \binom{h^3 k^2 + \delta}{\mu-1} + k$ ;  $\delta$  is the source node degree*

# Bound for the General Case

## Theorem

*Secure linear network codes for a wiretap multicast network exist over  $GF(q)$ ,  $\forall q \geq \binom{N-1}{\mu-1} + k$ .*

## Theorem

*Secure linear network codes for a wiretap multicast network exist over  $GF(q)$ ,  $\forall q \geq \binom{h^3 k^2 + \delta}{\mu-1} + k$ ;  $\delta$  is the source node degree*

# Outline

# Summary

- We considered the problem of designing network code that will guaranty **security** in a network with **multicast demands**
- Building on an analogy with the **wiretap channel of type II**, we proposed using **coset codes** for the multicast channel
- We showed that coset codes are equivalent to other codes already studied in literature. Nevertheless, they permit an easy recovery of some important results.
- We also gave an **improved lower bound** on the field size sufficient for the existence of secure network code
