LIESSE
Fourier representation of random signals

François Roueff
Telecom ParisTech
May 17, 2018

Time series analysis based on stochastic modeling is applied in various fields:
- Health: physiological signal analysis (image analysis).
- Engineering: monitoring, anomaly detection, localizing/tracking.
- Audio data: analysis, synthesis, coding.
- Ecology: climatic data, hydrology.
- Econometrics: economic/financial data.
- Insurance: risk analysis.

Figure: Heart rate of a resting person over a period of 900 seconds. This rate is defined as the number of heartbeats per unit of time. Here the unit is the minute and is evaluated every 0.5 seconds.
Preliminaries

Weakly stationary processes

Random fields with orthogonal increments

Linear filtering in the spectral domain

Internet traffic

Figure: Inter-arrival times of TCP packets, expressed in seconds, obtained from a 2 hours record of the traffic going through an Internet link. http://ita.ee.lbl.gov/.

Speech audio data

Figure: A speech audio signal with a sampling frequency equal to 8000 Hz. Record of the unvoiced fricative phoneme sh (as in sharp).

Climatic data: wind speed

Figure: Daily record of the wind speed at Kilkenny (Ireland) in knots (1 knot = 0.5148 metres/second).

Climatic data: temperature changes

Figure: Global mean land-ocean temperature index (solid red line) and surface-air temperature index (dotted black line). http://data.giss.nasa.gov/gistemp/graphs/.
**Preliminaries**

- Weakly stationary processes
- Random fields with orthogonal increments
- Linear filtering in the spectral domain

**Gross National Product of the USA**

Stochastic modelling

Definition: time series
A time series valued in \((E, \mathcal{E})\) and indexed on \(T = \mathbb{Z}\) is a collection of random variables \((X_t)_{t \in T}\) defined on the same probability space \((\Omega, \mathcal{F}, \mathbb{P})\).

Definition: path
Let \((X_t)_{t \in T}\) be a random process defined on \((\Omega, \mathcal{F}, \mathbb{P})\). The path of the random experiment \(\omega \in \Omega\) is defined as \((X_t(\omega))_{t \in T}\) viewed as an element of \(E^T\).

Definition: law
Let \(X = (X_t)_{t \in T}\) be a random process. The law of \(X\) is defined as the image probability measure \(\mathbb{P}^X = \mathbb{P} \circ X^{-1}\) on \((E^T, \mathcal{E}^T)\).

Backshift operator, stationarity

Definition: backshift operators
Let the backshift operator \(B : E^\mathbb{Z} \to E^\mathbb{Z}\) be defined by
\[
B(x) = (x_{t-1})_{t \in \mathbb{Z}} \quad \text{for all} \quad x = (x_t)_{t \in \mathbb{Z}} \in E^\mathbb{Z}.
\]
For all \(\tau \in \mathbb{Z}\), we define \(B^\tau\) by
\[
B^\tau(x) = (x_{t-\tau})_{t \in \mathbb{Z}} \quad \text{for all} \quad x = (x_t)_{t \in \mathbb{Z}} \in E^\mathbb{Z}.
\]
A process \(X = (X_t)_{t \in T}\) is said to be stationary if \(X\) and \(B \circ X\) have the same distributions.

Examples: constant process, i.i.d. processes, Gaussian processes, ...

Finite dimensional (fidi) distributions

For all \(I \in \mathcal{I}(T)\) (a finite subset of \(T\)),

(i) denote by \(\Pi_I\) is the canonical projection \((x_t)_{t \in T} \mapsto (x_t)_{t \in I}\),

(ii) denote by \(X_I\) the random vector \((X_t)_{t \in I} = \Pi_I \circ X\),

(iii) denote by \(\mathbb{P}^{X_I}\) the distribution of \(X_I\), which is defined by
\[
\mathbb{P}^{X_I} \left( \prod_{t \in I} A_t \right) = \mathbb{P} (X_t \in A_t, t \in I), \quad \text{where} \ A_t \in \mathcal{E} \ \text{for all} \ t \in I.
\]

Remark: \(\mathbb{P}^{X_I}\) is characterized by the collection of fidi distributions \((\mathbb{P}^{X_I})_{I \in \mathcal{I}(T)}\).

\(L^2\) space

We set \(E = \mathbb{C}^d\). We denote
\[
L^2(\Omega, \mathcal{F}, \mathbb{P}) = \left\{ X \ \mathbb{C}^d\text{-valued r.v. such that} \ \mathbb{E} \left[ |X|^2 \right] < \infty \right\}.
\]

\((L^2, \langle \cdot, \cdot \rangle)\) is a Hilbert space with
\[
\langle X, Y \rangle = \mathbb{E} \left[ X^T Y \right].
\]

Definition: \(L^2\) Processes
The process \(X = (X_t)_{t \in T}\) defined on \((\Omega, \mathcal{F}, \mathbb{P})\) with values in \(\mathbb{C}^d\) is an \(L^2\) process if \(X_t \in L^2(\Omega, \mathcal{F}, \mathbb{P})\) for all \(t \in T\).
### Preliminaries

#### Mean and covariance functions

Let $X = (X_t)_{t \in T}$ be an $L^2$ process.

- Its **mean function** is defined by $\mu(t) = \mathbb{E}[X_t]$.
- Its **covariance function** is defined by
  \[ \Gamma(s, t) = \text{cov}(X_s, X_t) = \mathbb{E} [X_s X_t^H] - \mathbb{E} [X_s] \mathbb{E} [X_t]^H. \]

#### Linear combinations → scalar case

Let $X = (X_t)_{t \in T}$ be an $L^2$ process with mean function $\mu$ and covariance function $\Gamma$. This is equivalent to say that for all $u \in \mathbb{C}^d$, $u^H X$ is a scalar $L^2$ process with mean function $u^H \mu$ and covariance function $u^H \Gamma u$.

### Weakly stationary processes

Let $T = \mathbb{Z}$. Let $X$ be an $L^2$ strictly stationary process with mean function $\mu$ and covariance function $\Gamma$.

Then $\mu(t) = \mu(0)$ and $\gamma(s, t) = \gamma(s - t, 0)$ for all $s, t \in T$.

**Definition**: **Weak stationarity**

We say that a random process $X$ is weakly stationary with mean $\mu$ and autocovariance function $\gamma : \mathbb{Z} \to \mathbb{C}$ if it is $L^2$ with mean function $t \mapsto \mu$ and covariance function $(s, t) \mapsto \gamma(s - t)$.

The **autocorrelation function** is defined (when $\gamma(0) > 0$) by
\[ \rho(t) = \frac{\gamma(t)}{\gamma(0)}. \]

### Scalar case $E = \mathbb{C}$, examples

**Hermitian symmetry, non-negative definiteness**

For all $I \in \mathcal{I}(T)$, $\Gamma_I = \text{Cov}([X(t)]_{t \in I}) = [\gamma(s, t)]_{s, t \in I}$ is a hermitian non-negative definite matrix.

**Examples**

- $L^2$ independent random variables $(X_t)_{t \in \mathbb{Z}}$ have mean $\mu(t) = \mathbb{E}(X_t)$ and covariance
  \[ \Gamma(s, t) = \begin{cases} \text{var}(X_t) & \text{if } s = t, \\ 0 & \text{otherwise}. \end{cases} \]

- A **Gaussian process** is an $L^2$ process whose law is entirely determined by its mean and covariance functions.

### Strong and weak white noise

- A sequence of $L^2$ i.i.d. random variables is called a **strong white noise**, denoted by $X \sim \text{IID}(\mu, \sigma^2)$.
- An $L^2$ process $X$ with constant mean $\mu$ and constant diagonal covariance function equal to $\sigma^2$ is called a **weak white noise**. It is denoted by $X \sim \text{WN}(\mu, \sigma^2)$. (It does not have to be i.i.d.)
Examples based on stationarity preserving linear filters

Let $X$ be weakly stationary with mean $\mu$ and autocovariance $\gamma$.

In the following examples, $Y = g(X)$ is weakly stationary with mean $\mu'$ and autocovariance $\gamma'$.

- Let $g$ be the time reversing operator $(x_t)_{t \in \mathbb{Z}} \mapsto (x_{-t})_{t \in \mathbb{Z}}$. Then
  \[
  \mu' = \mu \quad \text{and} \quad \gamma' = \bar{\gamma} .
  \]

- Let $g = \sum_k \psi_k B^k : x \mapsto \psi x$ for a finitely supported sequence $\psi$. Then
  \[
  \mu' = \mu \sum_k \psi_k \\
  \gamma'(\tau) = \sum_{\ell,k} \psi_{\ell-k} \psi_k \bar{\gamma}(\tau + \ell - k) \quad (1)
  \]

Empirical estimates

Suppose you want to estimate the mean and the autocovariance from a sample $X_1, \ldots, X_n$. Define the empirical mean as

\[
\hat{\mu}_n = \frac{1}{n} \sum_{k=1}^n X_k ,
\]

and the empirical autocovariance and autocorrelation functions as

\[
\hat{\gamma}_n(h) = \frac{1}{n} \sum_{k=1}^{n-|h|} (X_k - \hat{\mu}_n)(X_{k+|h|} - \hat{\mu}_n) \quad \text{and} \\
\hat{\rho}_n(h) = \frac{\hat{\gamma}_n(h)}{\hat{\gamma}_n(0) .}
\]

Figure: $X_t$ VS $X_{t-1}$ for the heartbeats data (see Figure 4). The red dashed line is the best linear fit.
**Spectral measure**

Given a function $\gamma : \mathbb{Z} \to \mathbb{C}$, does there exist a weakly stationary process $(X_t)_{t \in \mathbb{Z}}$ with autocovariance $\gamma$?

**Herglotz Theorem**

Let $\gamma : \mathbb{Z} \to \mathbb{C}$. Then the two following assertions are equivalent:

(i) $\gamma$ is hermitian symmetric and non-negative definite.

(ii) There exists a finite non-negative measure $\nu$ on $T = \mathbb{R}/2\pi \mathbb{Z}$ such that,

$$
\gamma(t) = \int_T e^{i\lambda t} \nu(d\lambda) \quad (2)
$$

When these two assertions hold, $\nu$ is uniquely defined by (2).

**Examples**

- Let $X \sim \text{WN}(\mu, \sigma^2)$. Then $f(\lambda) = \frac{\sigma^2}{2\pi}$.
- Let $X$ be a weakly stationary process with covariance function $\gamma$ and spectral measure $\nu$. Define

$$Y = \sum_k \psi_k B^k \circ X$$

for a finitely supported sequence $\psi$. Recall that $Y$ is a weakly stationary process with covariance function $\gamma'(\tau) = \sum_{\ell,k} \psi_k \overline{\psi}_\ell \gamma(\tau + \ell - k)$.

Then $Y$ is a weakly stationary process with spectral measure $\nu'$ having density $\lambda \mapsto |\sum_k \psi_k e^{-i\lambda k}|^2$ with respect to $\nu$,

$$
\nu'(d\lambda) = \left|\sum_k \psi_k e^{-i\lambda k}\right|^2 \nu(d\lambda).
$$

**A special one: the harmonic process**

Let $(A_k)_{1 \leq k \leq N}$ be $N$ real valued $L^2$ random variables. Denote $\sigma_k^2 = \mathbb{E} \left[ A_k^2 \right]$. Let $(\psi_k)_{1 \leq k \leq N}$ be $N$ i.i.d. random variables with a uniform distribution on $[0, 2\pi]$, and independent of $(A_k)_{1 \leq k \leq N}$.

Define

$$X_t = \sum_{k=1}^N A_k \cos(\lambda_k t + \Phi_k),$$

where $(\lambda_k)_{1 \leq k \leq N} \in [-\pi, \pi]$ are $N$ frequencies. The process $(X_t)$ is called a harmonic process. It satisfies $\mathbb{E} [X_t] = 0$ and, for all $s, t \in \mathbb{Z}$,

$$
\mathbb{E} [X_s X_t] = \frac{1}{2} \sum_{k=1}^N \sigma_k^2 \cos(\lambda_k (s - t)).
$$

Hence $X$ is weakly stationary with autocovariance $\gamma(t) = \frac{1}{2} \sum_{k=1}^N \sigma_k^2 \cos(\lambda_k t)$. 

**Spectral density**

If moreover $\gamma \in \ell^1(\mathbb{Z})$, these assertions are equivalent to

$$f(\lambda) := \frac{1}{2\pi} \sum_{t \in \mathbb{Z}} e^{-i\lambda t} \gamma(t) \geq 0 \text{ for all } \lambda \in \mathbb{R},$$

and $\nu$ has density $f$ (that is, $\nu(d\lambda) = f(\lambda) d\lambda$).

**Definition: spectral measure and spectral density**

If $\gamma$ is the autocovariance of a weakly stationary process $X$, the corresponding measure $\nu$ is called the spectral measure of $X$. Whenever the spectral measure $\nu$ admits a density $f$, it is called the spectral density function.
Preliminaries Weakly stationary processes Random fields with orthogonal increments Linear filtering in the spectral domain

Spectral representation of the harmonic process
We deduce that $X$ has spectral measure
$$
\mu = \frac{1}{2} \sum_{k=1}^{N} \sigma_k^2 (\delta_{\lambda_k} + \delta_{-\lambda_k}),
$$
where we denote by $\delta_{\lambda}$ the Dirac mass at point $\lambda$.

Similarly, we can write
$$
X_t = \frac{1}{2} \sum_{k=1}^{N} (A_k e^{i\Phi_k} e^{i\lambda_k t} + A_k e^{-i\Phi_k} e^{-i\lambda_k t})
$$
$$
= \int_{\mathbb{T}} e^{i\lambda t} dW(\lambda),
$$
where $W$ is the random (complex valued) measure
$$
W = \frac{1}{2} \sum_{k=1}^{N} (A_k e^{i\Phi_k} \delta_{\lambda_k} + A_k e^{-i\Phi_k} \delta_{-\lambda_k}).
$$

Why is it useful?
Recall the backshift operator $B : (x_t)_{t \in \mathbb{Z}} \mapsto (x_{t-1})_{t \in \mathbb{Z}}$.

Observe that from
$$
X_t = \int_{\mathbb{T}} e^{i\lambda t} d\hat{X}(\lambda), \quad t \in \mathbb{Z},
$$
we get that
$$
(B X)_t = \int_{\mathbb{T}} e^{i\lambda t} e^{-i\lambda} d\hat{X}(\lambda) \Rightarrow dB(\hat{X})(\lambda) = e^{-i\lambda} d\hat{X}(\lambda).
$$

More generally, if $g = \sum_k \alpha_k B^k$ for some finitely supported sequence $(\alpha_t)_{t \in \mathbb{Z}}$, we get
$$
d\hat{g}(\lambda) = \hat{g}(\lambda) d\hat{X}(\lambda) \quad \text{with} \quad \hat{g}(\lambda) = \sum_k \alpha_k e^{-i\lambda k}.
$$

This will allow us to come up with linear operators $g$ directly described by the function $\hat{g}$ (under quite general conditions).

Spectral representation
One can interpret the relation between $X$ and $W$ as saying that $W$ is the Fourier transform of $X$, so we denote it by $\hat{X}$:
$$
X_t = \int_{\mathbb{T}} e^{i\lambda t} d\hat{X}(\lambda), \quad t \in \mathbb{Z}.
$$

This spectral representation of $X$ can be extended to any weakly stationary processes with some remarkable properties on $\hat{X}$.

Consequence
For all $A,B \in \mathcal{X}$ such that $A \cap B = \emptyset$, $W(A)$ and $W(B)$ are uncorrelated and $W(A \cup B) = W(A) + W(B)$.

Random fields with orthogonal increments
In the following we let $(\mathcal{X}, \mathcal{X})$ be a measurable space.

Definition: Random fields with orthogonal increments
Let $\eta$ be a finite non-negative measure on $(\mathcal{X}, \mathcal{X})$. Let $W = (W(A))_{A \in \mathcal{X}}$ be an $L^2$ process indexed by $\mathcal{X}$. It is called a random field with orthogonal increments and intensity measure $\eta$ if it satisfies the following conditions.

(i) For all $A \in \mathcal{X}$, $\mathbb{E} [W(A)] = 0$.

(ii) For all $A, B \in \mathcal{X}$, $\text{Cov}(W(A), W(B)) = \eta(A \cap B)$.

Consequence
For all $A, B \in \mathcal{X}$ such that $A \cap B = \emptyset$, $W(A)$ and $W(B)$ are uncorrelated and $W(A \cup B) = W(A) + W(B)$. 

Preliminaries Weakly stationary processes Random fields with orthogonal increments Linear filtering in the spectral domain

Conclusion
Example

We denote by $\delta_\lambda$ the Dirac mass at point $\lambda$.

Let $\lambda_k$, $k = 1, \ldots, n$ be fixed elements of $\mathcal{X}$. Let $Y_1, \ldots, Y_n$ be centered $L^2$ uncorrelated random variables with variances $\sigma_1^2, \ldots, \sigma_n^2$. Then

$$W = \sum_{k=1}^n Y_k \delta_{\lambda_k}$$

is a random field with orthogonal increments and intensity measure

$$\eta = \sum_{k=1}^n \sigma_k^2 \delta_{\lambda_k}.$$ 

Stochastic integral

Let $W$ be a random field with orthogonal increments defined on $(\Omega, \mathcal{F}, \mathbb{P})$, with intensity measure $\eta$ on $(\mathcal{X}, \mathcal{X})$.

The stochastic integral with respect to $W$ is defined by the following steps.

**Step 1** We set $W(\mathbb{1}_A) = W(A)$, which defines a unitary operator from $\{\mathbb{1}_A, A \in \mathcal{X}\} \subset L^2(\mathcal{X}, \mathcal{X}, \eta)$ to $L^2(\Omega, \mathcal{F}, \mathbb{P})$.

**Step 2** Extend this unitary operator linearly on $\operatorname{Span}(\mathbb{1}_A, A \in \mathcal{X})$.

**Step 3** Extend this unitary operator continuously to the $L^2$-sense closure $\overline{\operatorname{Span}(\mathbb{1}_A, A \in \mathcal{X})} = L^2(\mathcal{X}, \mathcal{X}, \eta)$.

**Step 4** One obtains a $L^2(\mathcal{X}, \mathcal{X}, \eta) \to L^2(\Omega, \mathcal{F}, \mathbb{P})$ centered unitary linear operator. We denote

$$W(g) = \int g \, dW \quad , \quad g \in L^2(\mathcal{X}, \mathcal{X}, \eta).$$

Conversely, any $L^2(\mathcal{X}, \mathcal{X}, \eta) \to L^2(\Omega, \mathcal{F}, \mathbb{P})$ centered unitary linear operator defines a random field $W$ with intensity measure $\eta$.

Construction of the spectral random field

Conversely, let $(X_t)_{t \in \mathbb{Z}}$ be a centered weakly stationary process with spectral measure $\eta$.

**Step 1** Define

$$\mathcal{H}_\infty^X = \overline{\operatorname{Span}(X_t, t \in \mathbb{Z})}.$$ 

**Step 2** As previously, we can extend $X_t \mapsto e^{it\cdot}$ linearly and continuously as a unitary linear operator from $\mathcal{H}_\infty^X$ to $L^2(\mathbb{T}, \mathcal{B}(\mathbb{T}), \eta)$.

**Step 3** Since $\overline{\operatorname{Span}(e^{it\cdot}, t \in \mathbb{Z})} = L^2(\mathbb{T}, \mathcal{B}(\mathbb{T}), \eta)$, this operator is bijective.

**Step 4** Let $\hat{X}$ be its inverse operator.

Then $\hat{X}$ is a random field with orthogonal increments with intensity measure $\eta$ on $(\mathbb{T}, \mathcal{B}(\mathbb{T}))$.
Spectral representation

Moreover, by construction, every \( Y \in \mathcal{H}_\infty^X \) can be represented as
\[
Y = \int g(\lambda) \, d\hat{X}(\lambda) .
\]
for a (unique) well chosen \( g \in L^2(\mathbb{T}, \mathcal{B}(\mathbb{T}), \eta) \).

In particular, for all \( t \in \mathbb{Z} \),
\[
X_t = \int e^{it\lambda} \, d\hat{X}(\lambda) .
\]
and \( \hat{X} \) is called the spectral representation of \( X \).

Example: complex-valued Harmonic processes

The previous definition of harmonic processes can be extended as follows.

**Definition : Harmonic processes**

The process \((X_t)_{t \in \mathbb{Z}}\) is an harmonic process if its spectral representation \( \hat{X} \) is of the form
\[
\hat{X} = \sum_{k=1}^n Z_k \delta_{\lambda_k} ,
\]
where \( \lambda_1, \ldots, \lambda_n \) are deterministic frequencies in \( \mathbb{T} \) and \( Z_1, \ldots, Z_n \) are uncorrelated centered \( \mathbb{C} \)-valued random variables.

Example: real-valued Harmonic processes

To obtained a real valued process \( \hat{X} \) must satisfy an hermitian symmetry
\[
\hat{X}(-A) = \overline{X(A)}.
\]

Hence, for a real valued harmonic process, we obtain for \( 0 < \lambda_0 < \cdots < \lambda_n \leq \pi \),
\[
\hat{X} = Z_0 \delta_0 + \sum_{k=1}^N (Z_k \delta_{\lambda_k} + \overline{Z}_k \delta_{-\lambda_k}) ,
\]
where \( Z_0, Z_1, \ldots, Z_N, \overline{Z}_1, \ldots, \overline{Z}_N \) are uncorrelated centered \( \mathbb{C} \)-valued random variables and \( Z_0 \) is real valued.

(Recall our previous example where \( Z_k = \frac{1}{2} A k e^{i \phi_k} \).)

Examples

**Centered white noise**

If \((X_t)_{t \in \mathbb{Z}} \sim \text{WN}(0, \sigma^2)\) then \( \hat{X} \) satisfies
\[
\text{Var} \left( \hat{X}(\lambda', \lambda) \right) = \frac{\sigma^2}{2\pi} (\lambda - \lambda') , \quad \lambda' < \lambda < \lambda' + 2\pi .
\]

**Linear filtering**

Let \((X_t)_{t \in \mathbb{Z}}\) be centered, weakly stationary with spectral measure \( \nu \) and spectral representation \( \hat{X} \). Then for any \( g \in L^2(\mathbb{T}, \mathcal{B}(\mathbb{T}), \nu) \), one can define a centered, weakly stationary process \((Y_t)_{t \in \mathbb{Z}}\) by its spectral representation
\[
\hat{Y}(d\lambda) = \hat{g}(\lambda) \hat{X}(d\lambda) ,
\]
\[
Y_t = \int_T e^{it\lambda} \hat{Y}(d\lambda) = \int_T e^{it\lambda} \hat{g}(\lambda) \hat{X}(d\lambda) ,
\]
and \((Y_t)_{t \in \mathbb{Z}}\) is centered, weakly stationary with spectral measure \( \nu' \).
**A simple case: filtered white noise**

Let \((X_t)_{t \in \mathbb{Z}} \sim \text{WN}(0, \sigma^2)\). Then the following assertions are equivalent.

(i) The sum \(Y_t = \sum_{k \in \mathbb{Z}} \psi_k X_{t-k}\) converges in in \(L^2\).

(ii) The sequence \((\psi_t)_{t \in \mathbb{Z}} \in \ell^2\).

Convergence in \(L^2\) is sufficient to obtain as for \(\ell^1\) convolution filtering that \(Y\) is weakly stationary with spectral density \(f(\lambda) = \frac{\sigma^2}{2\pi} |\psi^*(\lambda)|^2\), where \(\psi^*\) is the transfer function

\[
\psi^*(\lambda) = \sum_{k \in \mathbb{Z}} \psi_k e^{-i\lambda k}.
\]

Hence the condition \(\psi \in \ell^1\) is too strong in this case.

**General linear time-invariant filtering**

Let \((X_t)_{t \in \mathbb{Z}}\) be a centered weakly stationary process with an arbitrary spectral measure \(\nu\).

We can generalize \(\ell^1\) convolution filtering by setting

\[
Y_t = \lim_{n \to \infty} \sum_{k \in \mathbb{Z}} \psi_{n,k} X_{t-k},
\]

where \((\psi_{n,k})_{k \in \mathbb{Z}}\) has finite support for all \(n\) and the limit holds in \(L^2\).

The spectral representation of this limit takes the general form

\[
Y_t = \int e^{i\lambda t} g(\lambda) \, d\tilde{X}(\lambda), \quad t \in \mathbb{Z},
\]

where \(g \in L^2(\mathbb{T}, B(\mathbb{T}), \nu)\). We shall denote

\[
Y = \hat{F}_g(X).
\]
