

An Information-Theoretic Approach to Joint Sensing and Communication

Mehrasa Ahmadipour, Mari Kobayashi, Michèle Wigger, Giuseppe Caire

Abstract

A communication setup is considered where a transmitter wishes to convey a message to a receiver and simultaneously estimate the state of that receiver through a common waveform. The state is estimated at the transmitter by means of generalized feedback, i.e., a strictly causal channel output, and the known waveform. The scenario at hand is motivated by joint radar and communication, which aims to co-design radar sensing and communication over shared spectrum and hardware. For the case of memoryless single receiver channels with i.i.d. time-varying state sequences, we fully characterize the capacity-distortion tradeoff, defined as the largest achievable rate below which a message can be conveyed reliably while satisfying some distortion constraints on state sensing. We propose a numerical method to compute the optimal input that achieves the capacity-distortion tradeoff. Then, we address memoryless state-dependent broadcast channels (BCs). For physically degraded BCs with i.i.d. time-varying state sequences, we characterize the capacity-distortion tradeoff region as a rather straightforward extension of single receiver channels. For general BCs, we provide inner and outer bounds on the capacity-distortion region, as well as a sufficient condition when this capacity-distortion region is equal to the product of the capacity region and the set of achievable distortions. A number of illustrative examples demonstrates that the optimal co-design schemes outperform conventional schemes that split the resources between sensing and communication.

I. INTRODUCTION

Future generation wireless networks are expected to support a number of autonomous and intelligent applications that strongly rely on accurate sensing and localization techniques [3]. The key-enabler of these applications is the ability to continuously sense the dynamically changing environment, hereafter called the *state*, and to react accordingly by *exchanging information* between nodes. Although most current systems have separate implementations of sensing and communication systems, the high cost of spectrum and hardware encourages integrating both tasks via a single waveform and a single hardware platform (see e.g. [4], [5] and references therein). A typical example is joint radar sensing and communication, where a transmitter equipped with a co-located radar receiver wishes to convey a message to a (already detected) receiver and simultaneously estimate state parameters of that receiver. The scenario at hand has been extensively studied in the literature (see e.g. [6], [7] and references therein). In particular, a number of joint sensing and communication schemes, or co-design schemes, have been proposed to optimize performance metrics capturing some tension between two functions [8]–[12]. Although these works provide system guidelines or propose waveforms suitable to some specific scenarios, none has addressed the fundamental performance limits above which a joint sensing and communication system cannot operate irrespectively of computational complexities, choices of state parameters, or further assumptions.

Such an observation motivates us to study the fundamental limit of joint sensing and communication from an information theoretical perspective. To this end, we build on a simple single-user communication model where a transmitter exploits strictly causal channel output, or *generalized feedback*, for state sensing while a receiver has perfect state knowledge [1]. The proposed model captures two underlying assumptions used in radar signal processing. On the one hand, generalized feedback captures the inherently passive nature of the backscattered signal observed at the transmitter, which cannot be controlled but is determined by its surrounding environment. On the

Parts of the materials were presented at IEEE Int. Symp. Inf. Theory (ISIT) 2018 and IEEE Inf. Theory Workshop (ITW) 2020 [1], [2]. M. Ahmadipour and M. Wigger are with LTCI, Telecom Paris, IP Paris, F-91120 Palaiseau, France, {mehrasa.ahmadipour,michele.wigger}@telecom-paris.fr.

Kobayashi and G. Caire is supported by the DFG, Grant agreement numbers KR 3517/11-1 and CA 1340/11-1, respectively.

other hand, state sensing is performed based on a known waveform as it is chosen by the transmitter itself. The goal is to design a synergistic waveform that optimizes some tradeoffs between sensing and communication qualities. Towards this goal, we consider the *capacity-distortion tradeoff* that suitably balances between two ultimate goals, i.e. maximizing the communication rate and minimizing the state estimation error or distortion. Notice that the capacity-distortion tradeoff has been studied in the context of so-called state communication, where a transmitter with state knowledge wishes to convey the state to a receiver with no state knowledge [13]–[15].

Under this setup, we first address a simple point-to-point channel where a transmitter sends a message to a receiver while estimating the corresponding state. Our objective is to characterize the capacity-distortion-cost tradeoff of state-dependent discrete memoryless channels with i.i.d. time-varying states and then quantify the merit with respect to the following two baseline schemes: i) a basic time-sharing (TS) scheme that performs either sensing or communication; ii) an improved TS scheme that prioritizes either sensing or communication and chooses the transmit waveform according to this priority, but then uses this waveform to perform both tasks. The basic TS scheme applies to the restricted case where two systems co-exist but cannot cooperate with each other. Albeit very naive, it captures the constraint of a separation-based conventional system that estimates the state via a sensing waveform carrying no information and sends data via a communication waveform which is completely ignored during the sensing task. In contrast, an improved TS scheme can be interpreted as a first step towards a co-design scheme that uses a single waveform for both communication and sensing tasks.

Then, we consider a two-user broadcast channel (BC) where a transmitter sends messages to two receivers and simultaneously estimates the respective states. For simplicity, we assume that each receiver knows the respective state perfectly. Completely characterizing the capacity-distortion tradeoff region for a general memoryless state-dependent BC seems extremely challenging, since even the capacity region (without sensing) is unknown both in the case without and with feedback (see e.g., [16]–[18]). Therefore, we start with the simpler special case of state-dependent physically degraded BCs, for which capacity is known and is the same with and without feedback. In this paper we extend this result to include sensing and characterize the capacity-distortion region of state-dependent physically degraded BCs with generalized feedback. Analogously to the single-user case, feedback is useful only for sensing but not for communication.

For general BCs, feedback can enlarge capacity because it enables the transmitter to send some common information that is useful to both receivers at the same time (see e.g., [19, Section 17]). In this paper we extend this intuition to a setup that includes sensing, and we provide general inner and outer bounds on the capacity-distortion region for general memoryless BCs with generalized feedback. A similar achievability result for joint sensing and communication has previously also been presented for memoryless multiple access channels [20].

A. Contribution

The paper provides the following technical contributions:

- 1) It characterizes the capacity-distortion-cost tradeoff of state-dependent memoryless channels in Theorem 1 and states the optimal estimator (a deterministic symbol-by-symbol estimator) in Lemma 1. A modified Blahut-Arimoto algorithm [21], [22] is proposed to numerically calculate the tradeoff region. To this end, optimality of an alternating optimization approach is proved in Theorem 2.
- 2) As a rather straightforward extension of Theorem 1, we characterize the capacity-distortion tradeoff region of physically degraded state-dependent memoryless broadcast channels in Theorem 3.
- 3) For general state-dependent BCs, we provide an outer bound on the capacity-distortion region in Theorem 4 and an inner bound in Proposition 1. The inner bound is based on [16] and can be achieved using a block-Markov strategy that combines Marton coding with a lossy version of Gray-Wyner coding with side-information.
- 4) Corollary 1 (for single-user channels) and Proposition 2 (for broadcast channels) identify sufficient conditions for channels where no capacity-distortion tradeoff arises.
- 5) A number of illustrative examples are provided to demonstrate the benefits of the optimal co-design scheme compared to the aforementioned baseline schemes. These include a binary channel with a multiplicative Bernoulli state in Corollary 2, a real Gaussian channel, a binary BC with multiplicative Bernoulli states in Corollaries 3 and 4, as well as the state-dependent Dueck BC in Corollaries 7 and 8.

Fig. 1. Joint Sensing and Communication Model

B. Organization

The rest of this paper is organized as follows. The following Section II describes the model, formulates the joint sensing and communication problem in a single-receiver channel, and provides the corresponding capacity-distortion-cost tradeoff. Section III extends the obtained results to two-user broadcast channels. Finally, Section IV concludes the paper.

C. Notation

We use calligraphic letters to denote sets, e.g., \mathcal{X} . The sets of real and nonnegative real numbers however are denoted by \mathbb{R} and \mathbb{R}_0^+ . Random variables are denoted by uppercase letters, e.g., X , and their realizations by lowercase letters, e.g., x . For vectors we use boldface notation, i.e., lower case boldface letters such as \mathbf{x} for deterministic vectors.

We use $[1 : X]$ to denote the set $\{1, \dots, X\}$. We use X^n for the tuple of random variables (X_1, \dots, X_n) . We abbreviate *independent and identically distributed* as *i.i.d.* and *probability mass function* as *pmf*. Logarithms are taken with respect to base 2.

II. A SINGLE RECEIVER

A. System Model

Consider the point-to-point communication scenario depicted in Fig. 1, where a transmitter wishes to communicate a message to a receiver over a memoryless state-dependent channel and simultaneously estimate the state from generalized feedback. In order to formulate the joint sensing and communication problem, we consider a state-dependent memoryless channel such that the channel output at the receiver Y_i and the feedback signal Z_i of a given time i are generated according to its stationary channel law $P_{YZ|XS}(\cdot, \cdot | x_i, s_i)$ given the time- i channel input $X_i = x_i$ and state realization $S_i = s_i$, irrespective of the past inputs, outputs and state signals. Except for some Gaussian examples, we assume that channel states S_i , inputs X_i , outputs Y_i , and feedback signals Z_i take value in given finite sets \mathcal{S} , \mathcal{X} , \mathcal{Y} , and \mathcal{Z} , respectively. The state sequence $\{S_i\}_{i \geq 1}$ is assumed i.i.d. according to a given state distribution $P_S(\cdot)$ and perfectly known to the receiver.

A $(2^{nR}, n)$ code for the state-dependent memoryless channel (SDMC) consists of

- 1) a discrete message set \mathcal{W} of size $|\mathcal{W}| \geq 2^{nR}$;
- 2) a sequence of encoding functions $\phi_i: \mathcal{W} \times \mathcal{Z}^{i-1} \rightarrow \mathcal{X}$, for $i = 1, 2, \dots, n$;
- 3) a decoding function $g: \mathcal{S}^n \times \mathcal{Y}^n \rightarrow \mathcal{W}$;
- 4) a state estimator $h: \mathcal{X}^n \times \mathcal{Z}^n \rightarrow \hat{\mathcal{S}}^n$, where $\hat{\mathcal{S}}$ denotes a given finite reconstruction alphabet.

For a given code, the random message W is uniformly distributed over the message set \mathcal{W} and the inputs are obtained as $X_i = \phi_i(W, Z^{i-1})$, for $i = 1, \dots, n$. The corresponding channel outputs Y_i and Z_i at time i are obtained from the state S_i and the input X_i according to the SDMC transition law $P_{YZ|SX}$. Let $\hat{S}^n := (\hat{S}_1, \dots, \hat{S}_n) = h(X^n, Z^n)$ denote the state estimate at the transmitter and $\hat{W} = g(S^n, Y^n)$ the decoded message at the receiver.

The quality of the state estimates is measured by the expected average per-block distortion

$$\Delta^{(n)} := \mathbb{E}[d(S^n, \hat{S}^n)] = \frac{1}{n} \sum_{i=1}^n \mathbb{E}[d(S_i, \hat{S}_i)] \quad (1)$$

where $d : \mathcal{S} \times \hat{\mathcal{S}} \mapsto \mathbb{R}_0^+$ is a given bounded *distortion function*:

$$\max_{(s, \hat{s}) \in \mathcal{S} \times \hat{\mathcal{S}}} d(s, \hat{s}) < \infty. \quad (2)$$

In practical communication systems, we typically impose an expected cost constraint on the channel inputs such as an average or peak power constraint. These cost constraints can often be expressed as

$$\mathbb{E}[b(X^n)] = \frac{1}{n} \sum_{i=1}^n \mathbb{E}[b(X_i)] \quad (3)$$

for some given cost functions $b : \mathcal{X} \mapsto \mathbb{R}_0^+$.

Definition 1. A rate-distortion-cost tuple (R, D, B) is said *achievable* if there exists a sequence (in n) of $(2^{nR}, n)$ codes that simultaneously satisfy

$$\lim_{n \rightarrow \infty} P_e^{(n)} = 0, \quad (4a)$$

$$\overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \mathbb{E}[d(S_i, \hat{S}_i)] \leq D, \quad (4b)$$

$$\overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \mathbb{E}[b(X_i)] \leq B \quad (4c)$$

for $P_e^{(n)} := \Pr(\hat{W} \neq W)$.

The capacity-distortion-cost tradeoff $C(D, B)$ is the largest rate R such that the rate-distortion-cost tuple (R, D, B) is achievable.

The main result of this section is an exact characterization of $C(D, B)$. We begin by describing the optimal estimator h , which is independent of the choice of encoding and decoding functions, and operates on a symbol-by-symbol basis, i.e., it computes estimate \hat{S}_i only in function of X_i and Z_i but not the other inputs and feedback signals.

Lemma 1. Define the function

$$\hat{s}^*(x, z) := \arg \min_{s' \in \hat{\mathcal{S}}} \sum_{s \in \mathcal{S}} P_{S|XZ}(s|x, z) d(s, s'), \quad (5)$$

where ties can be broken arbitrarily and

$$P_{S|XZ}(s|x, z) = \frac{P_S(s) P_{Z|SX}(z|s, x)}{\sum_{\tilde{s} \in \hat{\mathcal{S}}} P_S(\tilde{s}) P_{Z|SX}(z|\tilde{s}, x)}. \quad (6)$$

Irrespective of the choice of encoding and decoding functions, distortion $\Delta^{(n)}$ in (4b) is minimized by the estimator

$$h^*(x^n, z^n) := (\hat{s}^*(x_1, z_1), \hat{s}^*(x_2, z_2), \dots, \hat{s}^*(x_n, z_n)), \quad (7)$$

which only depends on the SDMC channel law $P_{Y|ZX}$ and the state distribution P_S .

Proof: See Appendix A. ■

Lemma 1 implies that we can focus without loss of generality on a symbol-by-symbol deterministic estimator. Based on (5), we define the estimation cost $c(x)$ of the optimal estimator as

$$c(x) := \mathbb{E}[d(S, \hat{s}^*(X, Z)) | X = x]. \quad (8)$$

Now we are ready to present the capacity-distortion-cost tradeoff.

B. Capacity-Distortion-Cost Tradeoff

In order to characterize some useful properties of the capacity-distortion-cost function, we define the following sets:

$$\mathcal{P}_D = \left\{ P_X \mid \sum_{x \in \mathcal{X}} P_X(x)c(x) \leq D \right\}, \quad (9a)$$

$$\mathcal{P}_B = \left\{ P_X \mid \sum_{x \in \mathcal{X}} P_X(x)b(x) \leq B \right\}. \quad (9b)$$

Then, the minimum distortion for a given cost B is given by

$$D_{\min}(B) := \min_{P_X \in \mathcal{P}_B} \sum_{x \in \mathcal{X}} P_X(x)c(x). \quad (10)$$

Definition 2. Define the information-theoretic tradeoff function $C_{\text{inf}} : [D_{\min}(B), \infty) \times [0, \infty) \rightarrow \mathbb{R}_0^+$ as

$$C_{\text{inf}}(D, B) := \max_{P_X \in \mathcal{P}_D \cap \mathcal{P}_B} I(X; Y | S) \quad (11)$$

where $(X, S, Y, Z) \sim P_X P_S P_{Y|Z|SX}$ and the maximum is over all P_X satisfying both the distortion and cost constraints (9a) and (9b).

Lemma 2. Given a SDMC $P_{Y|Z|SX}$ with state-distribution P_S , the capacity-distortion-cost tradeoff function $C_{\text{inf}}(D, B)$ has following properties.

- i) $C_{\text{inf}}(D, B)$ is non-decreasing and concave in $D \geq D_{\min}(B)$ and $B \geq 0$.
- ii) $C_{\text{inf}}(D, B)$ saturates at the channel capacity:

$$C_{\text{inf}}(D, B) = C_{\text{NoEst}}(B), \quad \forall D \geq D_{\max}(B), \quad (12)$$

where $C_{\text{NoEst}}(B) := \max_{P_X \in \mathcal{P}_B} I(X; Y | S)$ denotes the classical channel capacity of the SDMC for a given cost B , and $D_{\max}(B)$ denotes the corresponding distortion

$$D_{\max}(B) := \sum_{x \in \mathcal{X}} P_{X_{\max}}(x)c(x). \quad (13)$$

for $P_{X_{\max}} := \text{argmax}_{P_X \in \mathcal{P}_B} I(X; Y | S)$.

Proof: The proof is a straightforward extension of [14, Corollary 1] to the case of two cost functions and the state dependent channel. The nondecreasing property follows immediately from the definition (11) because we have $\mathcal{P}_{D_1} \subseteq \mathcal{P}_{D_2}$ and $\mathcal{P}_{B_1} \subseteq \mathcal{P}_{B_2}$ for any $D_1 \leq D_2$ and $B_1 \leq B_2$.

In order to verify the concavity of $C_{\text{inf}}(D, B)$ with respect to (D, B) , we consider time-sharing between two input distributions, denoted by $P_X^{(1)}$ and $P_X^{(2)}$, that achieve $C_{\text{inf}}(D_1, B_1)$, $C_{\text{inf}}(D_2, B_2)$, respectively. To make the dependency of the mutual information with respect to the input distribution more explicit, we adapt the following notation: for any pmf P_X over the input alphabet \mathcal{X} , let $\mathcal{I}(P_X, P_{Y|XS} | P_S) := I(X; Y | S)$ for $(S, X, Y) \sim P_S P_X P_{Y|XS}$.

For any $\theta \in (0, 1)$, we have:

$$\begin{aligned} \theta C_{\text{inf}}(D_1, B_1) + (1 - \theta) C_{\text{inf}}(D_2, B_2) &\stackrel{(a)}{=} \theta \mathcal{I}(P_X^{(1)}, P_{Y|XS} | P_S) + (1 - \theta) \mathcal{I}(P_X^{(2)}, P_{Y|XS} | P_S) \\ &\stackrel{(b)}{\leq} \mathcal{I}(\theta P_X^{(1)} + (1 - \theta) P_X^{(2)}, P_{Y|XS} | P_S) \\ &\stackrel{(c)}{=} C_{\text{inf}}(\theta D_1 + (1 - \theta) D_2, \theta B_1 + (1 - \theta) B_2). \end{aligned} \quad (14)$$

where (a) follows by definition, (b) follows from the concavity of the mutual information functional with respect to the input distribution, (c) follows by the linearity of the constraints and because for any $k = 1, 2$ the pmf $P_X^{(k)}$ has expected cost no larger than B_k and expected distortion no larger than D_k . This establishes the concavity of $C_{\text{inf}}(D, B)$. ■

We now state the main result of this section.

Theorem 1. *The capacity-distortion-cost tradeoff of a SDMC $P_{YZ|SX}$ with state-distribution P_S is:*

$$C(D, B) = C_{\text{inf}}(D, B), \quad D \geq D_{\text{min}}(B), \quad B \geq 0. \quad (15)$$

Proof: See Appendix B. ■

Combining Lemma 2 and Theorem 1, we can conclude that the rate-distortion tradeoff function $C(D, B)$ is non-decreasing and concave in $D \geq D_{\text{min}}$ and $B \geq 0$, and for any $B \geq 0$ it saturates at the channel capacity $C_{\text{NoEst}}(B)$.

For many channels, given $B \geq 0$, the tradeoff $C(D, B)$ is strictly increasing in D until it reaches $C_{\text{NoEst}}(B)$. However, for SDMCs and costs $B \geq 0$ where the capacity-achieving input distribution $P_{X_{\text{max}}} := \text{argmax}_{P_X \in \mathcal{P}_B} I(X; Y | S)$ also achieves minimum distortion $D_{\text{min}}(B)$, the capacity-distortion tradeoff is constant $C(D, B) = C_{\text{NoEst}}(B)$, irrespective of the allowed distortion D . This is in particular the case, when the expected distortion $\mathbb{E}[d(S, \hat{s}^*(X, Z))]$ does not depend on the input distribution P_X . The following corollary identifies a set of SDMCs $P_{YZ|SX}$ and state distributions P_S where this holds for all costs $B \geq 0$.

Corollary 1. *Assume that there exists a function $\psi(\cdot)$ with domain $\mathcal{X} \times \mathcal{Z}$ so that irrespective of the input distribution P_X the following two conditions hold:*

$$(S, \psi(X, Z)) \perp X, \quad (16)$$

$$S \text{---} \psi(X, Z) \text{---} (X, Z), \quad (17)$$

for $(S, X, Z) \sim P_S P_X P_{Z|SX}$. In this case, for any given B , the rate-distortion tradeoff function $C(D, B)$ is constant over $D \geq D_{\text{min}}$ and equal to the channel capacity of the SDMC:

$$C(D, B) = C_{\text{NoEst}}(B), \quad \forall D \geq D_{\text{min}}(B), \quad B \geq 0. \quad (18)$$

Proof: See Appendix C. ■

The following state-dependent erasure channel satisfies the conditions in above corollary. Let S be Bernoulli- p and Y equal to the erasure symbol “?” when $S = 1$ and $Y = X$ when $S = 0$. Moreover, assume perfect output feedback, i.e., $Y = Z$. For the choice $\psi(X, Z) = \mathbb{1}\{Z = \text{“?”}\} = S$ both Markov chains in Corollary 1 are trivially satisfied because S and X are independent.

C. Blahut-Arimoto Type Algorithm to evaluate Theorem 1

Through simple time-sharing arguments, it can be shown that for given feasible B , the set of achievable (R, D) pairs is convex. Its boundary is thus characterized by solving the following parameterized optimization problem for each $\mu \geq 0$:

$$\max_{P_X \in \mathcal{P}_B} \left[\mathcal{I}(P_X, P_{Y|XS} | P_S) - \mu \sum_{x \in \mathcal{X}} P_X(x) c(x) \right]. \quad (19)$$

Notice that the conditional mutual information functional can explicitly be written as:

$$\mathcal{I}(P_X, P_{Y|XS} | P_S) = \sum_{x \in \mathcal{X}} \sum_{s \in \mathcal{S}} \sum_{y \in \mathcal{Y}} P_S(s) P_X(x) P_{Y|XS}(y|xs) \log \frac{P_{Y|XS}(y|xs)}{P_{Y|S}(y|s)}. \quad (20)$$

for the state pmf P_S and the SDMC transition law $P_{YZ|XS}$.

Notice that for $\mu = 0$ we simply obtain the capacity of the SDMC under the input cost constraint (disregarding the distortion constraint), while for $\mu \rightarrow \infty$, we obtain the minimum possible distortion subject to the same input cost constraint. We remark that the parameterized optimization problem above differs from the standard Blahut-Arimoto algorithm with cost constraints [22, Section IV] only in that 1) the objective function (19) includes an additional penalty term and 2) the mutual information functional is $I(X; Y | S)$ instead of $I(X; Y)$, which reflects the state-dependent channel and the state knowledge at the receiver. Since the penalty term is additive and linear in P_X , all concavity properties desired for a Blahut-Arimoto type algorithm remain valid. The following Theorem 2 can then be proved by standard alternating optimization techniques, in analogy to the proof of the Blahut-Arimoto algorithm [21], [22].

By letting $Q_{X|YS}$ denote a general conditional pmf of X given Y, S , we consider the function:

$$J_\mu(P_X, P_{Y|XS}, P_S, Q_{X|YS}) = \sum_{x \in \mathcal{X}} \sum_{s \in \mathcal{S}} \sum_{y \in \mathcal{Y}} P_X(x) P_S(s) P_{Y|XS}(y|xs) \log \frac{Q_{X|YS}(x|ys)}{P_X(x)} - \mu \sum_{x \in \mathcal{X}} P_X(x) c(x) \quad (21)$$

Theorem 2. Let the state pmf P_S and the SDMC transition law $P_{Y|XS}$ be given. The following statements hold:
a) For each $\mu \geq 0$, denote by $L_\mu(\mathbf{B})$ the optimal value of (19). Then,

$$L_\mu(\mathbf{B}) = \max_{P_X \in \mathcal{P}(\mathbf{B})} \max_{Q_{X|YS}} J_\mu(P_X, P_S, P_{Y|XS}, Q_{X|YS}). \quad (22)$$

b) Fix $P_X \in \mathcal{P}(\mathbf{B})$. Then, $J_\mu(P_X, P_S, P_{Y|XS}, Q_{X|YS})$ is maximized by choosing $Q_{X|YS}$ as

$$Q_{X|YS}^*(x|ys) = \frac{P_X(x) P_{Y|XS}(y|xs)}{\sum_{x'} P_X(x') P_{Y|XS}(y|x's)}. \quad (23)$$

c) Fix $Q_{X|YS}$. Then, $J_\mu(P_X, P_S, P_{Y|XS}, Q_{X|YS})$ is maximized by choosing $P_X \in \mathcal{P}(\mathbf{B})$ as

$$P_X^*(x) = \frac{e^{g(x)}}{\sum_{x'} e^{g(x')}}, \quad x \in \mathcal{X}, \quad (24)$$

where

$$g(x) = \sum_s \sum_y P_S(s) P_{Y|XS}(y|xs) \log Q_{X|YS}(x|ys) - \lambda b(x) - \mu c(x) \quad (25)$$

and $\lambda \geq 0$ is chosen so that $\sum_{x \in \mathcal{X}} P_X(x) b(x) \leq B$ holds with equality when evaluated for P_X^* in (24). \square

Based on Theorem 2, we propose the following algorithm summarized in Algorithm 1. The algorithm yields a pair of capacity-distortion values $(C_\mu(\mathbf{B}), D_\mu(\mathbf{B}))$ for any fixed input cost B and μ . Letting $P_{X,\mu}^\infty$ denote the convergent input distribution produced by the algorithm for given B and μ , we have

$$C_\mu(\mathbf{B}) = \mathcal{I}(P_{X,\mu}^{(\infty)}, P_{Y|XS} | P_S) \quad (26a)$$

$$D_\mu(\mathbf{B}) = \sum_x c(x) P_{X,\mu}^{(\infty)}(x). \quad (26b)$$

By varying μ , we obtain the capacity-distortion tradeoff for fixed input cost B . Moreover, by varying the input cost B , we obtain the family of all such tradeoffs, and therefore the whole boundary of the achievable capacity-distortion-cost tradeoff region.

D. Examples

Before presenting our examples, we present two baseline schemes.

1) *Baseline Schemes:* We consider two baseline schemes that time share (TS) between two operating modes. The first baseline scheme, termed *Basic TS scheme*, is unable to simultaneously perform the sensing and communication tasks and splits its resources (time or bandwidth) between the following two modes:

- Sensing mode without communication (achieves rate-distortion pair $(0, D_{\min}(\mathbf{B}))$)

The input pmf P_X is chosen to minimize the distortion:

$$P_{X_{\min}} := \operatorname{argmin}_{P_X \in \mathcal{P}_{\mathbf{B}}} \sum_x P_X(x) c(x), \quad (30)$$

and thus the minimum distortion $D_{\min}(\mathbf{B})$ defined in (10) is achieved. Due to the lack of communication capability, the communication rate is zero.

- Communication mode without sensing (achieves $(C_{\text{NoEst}}(\mathbf{B}), D_{\text{trivial}}(\mathbf{B}))$)

Algorithm 1 Blahut-Arimoto Type Algorithm for SDMCs

 Fix $\mu \geq 0$.

- 1: **procedure** TRADEOFF ($C_\mu(\mathbf{B}), D_\mu(\mathbf{B})$)
- 2: Initialize $P_X^{(0)}(x) = \frac{1}{|\mathcal{X}|}$ for all $x \in \mathcal{X}$.
- 3: **for** $k = 1, 2, 3, \dots$ **do**
- 4:

$$Q_{X|YS}^{(k)}(x|ys) = \frac{P_X^{(k-1)}(x)P_{Y|XS}(y|xs)}{\sum_{x'} P_X^{(k-1)}(x')P_{Y|XS}(y|x's)}. \quad (27)$$

- 5: Choose $\lambda^{(0)} > 0$.
- 6: **for** $\ell = 1, 2, \dots$ **do**
- 7: Compute $p^{(\ell)}(x) = \frac{e^{g^{(\ell)}(x)}}{\sum_{x'} e^{g^{(\ell)}(x')}}$ with

$$g^{(\ell)}(x) = \sum_{s,y} P_S(s)P_{Y|XS}(y|xs) \log Q_{X|YS}^{(k)}(x|ys) - \lambda^{(\ell-1)}b(x) - \mu \sum_{(x,s,z) \in \mathcal{X} \times \mathcal{S} \times \mathcal{Z}} P_X(x)P_S(s)P_{Z|XS}(z|x,s)d(s,s^*(x,z)) \quad (28)$$

- 8: Update dual variables:

$$\lambda^{(\ell)} = \left[\lambda^{(\ell-1)} + \alpha_\ell \left(\sum_x b(x)p^{(\ell)}(x) - B \right) \right]_+ \quad (29)$$

▷ where α_ℓ is the gradient adaptation step

- 9: Let $P_X^{(k)}(x) = \lim_{\ell \rightarrow \infty} p^{(\ell)}(x)$.
-

The input pmf P_X is chosen to maximize the rate:

$$P_{X_{\max}} = \operatorname{argmax}_{P_X \in \mathcal{P}_{\mathcal{B}}} I(X; Y | S), \quad (31)$$

and this mode thus communicates at a rate equal to the channel capacity $C_{\text{NoEst}}(\mathbf{B})$. Due to the lack of proper sensing capabilities, the estimator is set to a constant value regardless of the feedback and the input signals. The mode thus achieves distortion

$$D_{\text{trivial}}(\mathbf{B}) := \min_{s' \in \hat{\mathcal{S}}} \sum_{s \in \mathcal{S}} P_S(s)d(s, s'). \quad (32)$$

The second baseline scheme is called *Improved TS scheme* and can simultaneously perform the communication and sensing tasks. This scheme time-shares between the following modes.

- Sensing mode with communication (achieves $(R_{\min}(\mathbf{B}), D_{\min}(\mathbf{B}))$)

The input pmf P_X is chosen according to (30) to achieve the minimum distortion. The chosen pmf $P_{X_{\min}}$ can achieve the following communication rate:

$$R_{\min} := I(X_{\min}; Y | S), \quad \text{for } X_{\min} \sim P_{X_{\min}}. \quad (33)$$

- Communication mode with sensing (achieves $(C_{\text{NoEst}}(\mathbf{B}), D_{\max}(\mathbf{B}))$)

The input pmf $P_{X_{\max}}$ is chosen as in (31) to maximize the communication rate. The mode thus communicates at the capacity $C_{\text{NoEst}}(\mathbf{B})$ of the channel. Sensing is performed by means of the optimal estimator in (5). The mode thus achieves distortion

$$D_{\max} := \sum_{x \in \mathcal{X}} P_{X_{\max}}(x)c(x), \quad \text{for } X_{\max} \sim P_{X_{\max}}. \quad (34)$$

It is worth noticing that for any cost $\mathbf{B} \geq 0$, the two operating points of the two modes in the Improved TS scheme, $(R_{\min}(\mathbf{B}), D_{\min}(\mathbf{B}))$ and $(C_{\text{NoEst}}(\mathbf{B}), D_{\max}(\mathbf{B}))$, also lie on the capacity-distortion-cost tradeoff curve

$C(D, B)$ presented in Theorem 1. These two points are thus also operating points of any optimal co-design scheme. As we will see at hand of the following examples, all other operating points of the Improved TS scheme are however typically suboptimal compared to an optimal co-design scheme.

2) *Example 1: Binary Channel with Multiplicative Bernoulli State:* Consider a channel $Y = SX$ with binary alphabets $\mathcal{X} = \mathcal{S} = \mathcal{Y} = \{0, 1\}$ and where the state S is Bernoulli- q , for $q \in (0, 1)$. We assume perfect output feedback to the transmitter $Y = Z$, and consider the Hamming distortion measure $d(s, \hat{s}) = s \oplus \hat{s}$. No cost constraint is imposed.

The following corollary specializes Theorem 1 to this example.

Corollary 2. *The capacity-distortion tradeoff of a binary channel with multiplicative Bernoulli state is given by*

$$C(D) = qH_b\left(\frac{D}{\min\{q, 1-q\}}\right), \quad (35)$$

where $H_b(p)$ denotes the binary entropy function. In other words, the curve $C(D)$ is parameterized as

$$\{(C = qH_b(p), D = p \min\{q, 1-q\}) : p \in [0, 1/2]\}. \quad (36)$$

Proof: Since Y is deterministic given S, X and in particular it equals 0 whenever $S = 0$, we have:

$$\begin{aligned} I(X; Y | S) &= P_S(0)H(Y | S = 0) + P_S(1)H(Y | S = 1) \\ &= P_S(1)H(X). \end{aligned} \quad (37)$$

Setting $p := P_X(0)$, we obtain

$$I(X; Y | S) = qH_b(p). \quad (38)$$

To calculate the distortion, we notice that the optimal estimator $\hat{s}^*(\cdot, \cdot)$ in Lemma 1 sets

$$\hat{s}^*(x, z) = \begin{cases} z, & \text{if } x = 1 \\ \operatorname{argmax}_{s \in \{0, 1\}} P_S(s), & \text{if } x = 0. \end{cases} \quad (39)$$

In fact, whenever $x = 1$ the transmitter acquires full state knowledge because $z = y = s$. In this case $c(x = 1) = 0$. For $x = 0$, the transmitter does not receive any useful information about the state and hence uses the best constant estimator, irrespective of the feedback z . In this case,

$$c(x = 0) = \mathbb{E} \left[d\left(S, \operatorname{argmax}_{s \in \{0, 1\}} P_S(s)\right) \middle| X = 0 \right] = \min_{s \in \{0, 1\}} P_S(s) = \min\{q, 1-q\}, \quad (40)$$

where we used the independence of S and X . The expected distortion of the optimal estimator thus evaluates to:

$$D = \sum_x P_X(x)c(x) = P_X(0)c(0) = p \min\{q, 1-q\}. \quad (41)$$

■

The capacity-distortion tradeoff of Corollary 2 is illustrated in Fig. 2 for state parameter $q = 0.4$. The figure also compares the performances of the two baseline TS schemes. We observe a significant gain of an optimal co-design scheme over the two TS baseline schemes. We conclude this example with a derivation of the parameters of the TS schemes.

The capacity-achieving input distribution is easily found as $P_{X_{\max}}(0) = P_{X_{\max}}(1) = 1/2$, and by (38) and (41) we find $C_{\text{NoEst}} = q$ and $D_{\max} = \min\{q, 1-q\}/2$. Minimum distortion $D_{\min} = 0$ is achieved by always sending $X = 1$, i.e., $P_{X_{\min}}(1) = 1$ and $P_{X_{\min}}(0) = 0$, in which case $D_{\min} = 0$ and $R_{\min} = 0$, see also (38) and (41). The Improved TS scheme thus achieves all pairs on the line connecting the two points $(0, 0)$ with $(q, \min\{q, 1-q\}/2)$. To determine the performance of the basic TS scheme, we recall that the best constant estimator (that does not consider the feedback) is $\hat{s}_{\text{const}} = \operatorname{argmax}_{s \in \{0, 1\}} P_S(s)$, which allows to conclude that $D_{\text{trivial}} = \min\{q, 1-q\}$. The basic TS scheme thus achieves all rate-distortion pairs on the line connecting the points $(0, 0)$ and $(q, \min\{q, 1-q\})$.

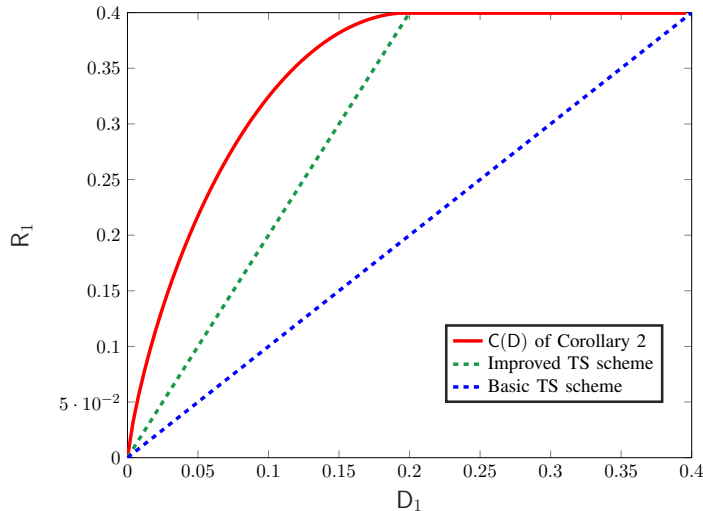

Fig. 2. Capacity-distortion tradeoff of the binary channel with multiplicative Bernoulli state of parameter $q = 0.4$.

Fig. 3. Capacity-distortion tradeoff of fading AWGN channel $B = 10$ dB and $\sigma_{\text{fb}}^2 = 1$.

3) *Example 2: Real Gaussian Channel with Rayleigh Fading:* We consider the real Gaussian channel with Rayleigh fading:

$$Y_i = S_i X_i + N_i, \quad (42)$$

where X_i is the channel input satisfying $\overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_i \mathbf{E}[|X_i|^2] \leq B = 10\text{dB}$, and both sequences $\{N_i\}$ and $\{S_i\}$ are independent of each other and i.i.d. Gaussian with zero mean and unit variance. The transmitter observes the noisy feedback

$$Z_i = Y_i + N_{\text{fb},i}, \quad (43)$$

where $\{N_{\text{fb},i}\}$ are i.i.d. zero-mean Gaussian of variance $\sigma_{\text{fb}}^2 \geq 0$. We consider the quadratic distortion measure $d(s, \hat{s}) = (s - \hat{s})^2$.

First, we characterize the two operating points achieved by the Improved TS baseline scheme. The capacity of this channel is achieved with a Gaussian input $X_{\text{max}} \sim \mathcal{N}(0, B)$, and thus the communication mode with sensing

achieves the rate-distortion pair

$$C_{\text{NoEst}}(\mathbf{B}) = \frac{1}{2} \mathbb{E} [\log(1 + |S|^2 \mathbf{B})] = 1.213, \quad D_{\text{max}}(\mathbf{B}) = (1 + \sigma_{\text{fb}}^2) \mathbb{E} \left[\frac{1}{1 + |X_{\text{max}}|^2 + \sigma_{\text{fb}}^2} \right] = 0.367, \quad (44)$$

where we have set $\sigma_{\text{fb}}^2 = 1$ and $P = 10\text{dB}$ to obtain the numerical values. Minimum distortion D_{min} is achieved by 2-ary pulse amplitude modulation (PAM), and thus the sensing mode with communication achieves rate-distortion pair

$$R_{\text{min}}(\mathbf{B}) = 0.733, \quad D_{\text{min}}(\mathbf{B}) = \frac{1 + \sigma_{\text{fb}}^2}{1 + P + \sigma_{\text{fb}}^2} = 0.166, \quad (45)$$

where the numerical value again corresponds to $\sigma_{\text{fb}} = 1$ and $B = 10\text{dB}$. Next, we characterize the performance of the basic TS baseline scheme. The best constant estimator for this channel is $\hat{s} = 0$, and the communication mode without sensing achieves rate-distortion pair $(C_{\text{NoEst}}(\mathbf{B}), D_{\text{trivial}}(\mathbf{B}) = 1)$. The sensing mode without communication achieves rate-distortion pair $(0, D_{\text{min}}(\mathbf{B}))$.

In Fig. 3, we compare the rate-distortion tradeoff achieved by these two TS baseline schemes with a numerical approximation of the capacity-distortion-cost tradeoff $C(D, \mathbf{B})$ of this channel. As previously explained, $C(D, \mathbf{B})$ also passes through the two end points $(R_{\text{min}}(\mathbf{B}), D_{\text{min}}(\mathbf{B}))$ and $(C_{\text{NoEst}}(\mathbf{B}), D_{\text{max}}(\mathbf{B}))$ of the Improved TS scheme. We use the Blahut-Arimoto type Algorithm 1 to obtain a numerical approximation of the points on $C(D, \mathbf{B})$ in between these two operating points. Specifically, the input alphabet is quantized to a $M = 16$ -ary PAM constellation $\mathcal{X}_q := \{(2m - 1 - M)\kappa, m = 1, \dots, M\}$ where $\kappa := \sqrt{3P/(M^2 - 1)}$. The Gaussian noise N is quantized with a centered equally-spaced 50-points alphabet, and the state S is quantized by applying an equally-spaced 8000-points quantizer on the Chi-square distributed random variable S^2 . Denoting the quantized input, noise, and state by X_q , N_q , and S_q , we keep our multiplicative-state, additive-noise channel model to generate the channel outputs used to run Algorithm 1 to obtain the numerical approximations:

$$Y_q = S_q X_q + N_q. \quad (46)$$

III. MULTIPLE RECEIVERS

In this section, we consider joint sensing and communication over two-receiver broadcast channels.

A. System Model

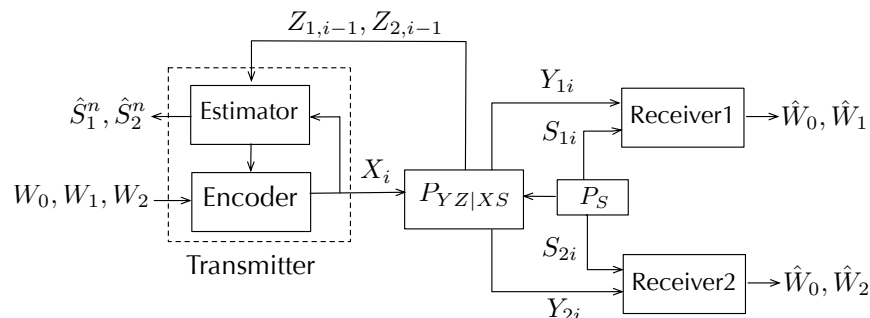

Fig. 4. State-dependent broadcast channel with generalized feedback and state-estimator at the transmitter.

Consider the two-receiver broadcast channel scenario depicted in Fig. 4. The model comprises a two-dimensional memoryless state sequence $\{(S_{1,i}, S_{2,i})\}_{i \geq 1}$ whose samples at any given time i are distributed according to a given joint law $P_{S_1 S_2}$ over the state alphabets $\mathcal{S}_1 \times \mathcal{S}_2$. Receiver 1 observes state sequence $\{S_{1,i}\}$ and Receiver 2 observes state sequence $\{S_{2,i}\}$. The transmitter communicates with both receivers over a state-dependent memoryless broadcast channel (SDMBC), where given time- i input $X_i = x$ and state realizations $S_{1,i} = s_1$ and $S_{2,i} = s_2$,

the time- i outputs $Y_{1,i}$ and $Y_{2,i}$ observed at the receivers and the transmitter's feedback signal Z_i are distributed according to the stationary channel transition law $P_{Y_1 Y_2 Z | S_1 S_2 X}(\cdot, \cdot, \cdot | s_1, s_2, x)$. We again assume that all alphabets $\mathcal{X}, \mathcal{Y}_1, \mathcal{Y}_2, \mathcal{Z}, \mathcal{S}_1, \mathcal{S}_2$ are finite.

The goal of the transmitter is to convey a common message W_0 to both receivers and individual messages W_1 and W_2 to Receivers 1 and 2, respectively, while estimating the states sequences $\{S_{1,i}\}$ and $\{S_{2,i}\}$ within some target distortions. For simplicity, the input cost constraint is omitted.

A $(2^{nR_0}, 2^{nR_1}, 2^{nR_2}, n)$ code for an SDMBC thus consists of

- 1) three message sets $\mathcal{W}_0 = [1 : 2^{nR_0}]$, $\mathcal{W}_1 = [1 : 2^{nR_1}]$, and $\mathcal{W}_2 = [1 : 2^{nR_2}]$;
- 2) a sequence of encoding functions $\phi_i: \mathcal{W}_0 \times \mathcal{W}_1 \times \mathcal{W}_2 \times \mathcal{Z}^{i-1} \rightarrow \mathcal{X}$, for $i = 1, 2, \dots, n$;
- 3) for each $k = 1, 2$ a decoding function $g_k: \mathcal{S}_k^n \times \mathcal{Y}_k^n \rightarrow \mathcal{W}_0 \times \mathcal{W}_k$;
- 4) for each $k = 1, 2$ a state estimator $h_k: \mathcal{X}^n \times \mathcal{Z}^n \rightarrow \hat{\mathcal{S}}_k^n$, where $\hat{\mathcal{S}}_1$ and $\hat{\mathcal{S}}_2$ are given reconstruction alphabets.

For a given code, we let the random messages W_0, W_1 , and W_2 be uniform over the message sets $\mathcal{W}_0, \mathcal{W}_1$, and \mathcal{W}_2 and the inputs $X_i = \phi_i(W_0, W_1, W_2, Z^{i-1})$, for $i = 1, \dots, n$. The corresponding outputs $Y_{1,i}, Y_{2,i}, Z_i$ at time i are obtained from the states $S_{1,i}$ and $S_{2,i}$ and the input X_i according to the SDMBC transition law $P_{Y_1 Y_2 Z | S_1 S_2 X}$. Further, for $k = 1, 2$ let $\hat{S}_k^n := (\hat{S}_{k,1}, \dots, \hat{S}_{k,n}) = h_k(X^n, Z^n)$ be the transmitter's estimates for state S_k^n and $(\hat{W}_{0,k}, \hat{W}_k) = g_k(S_k^n, Y_k^n)$ the messages decoded by Receiver k . The quality of the state estimates \hat{S}_k^n is again measured by bounded per-symbol distortion functions $d_k: \mathcal{S}_k \times \hat{\mathcal{S}}_k \mapsto [0, \infty)$, i.e., we assume

$$\max_{s_k \in \mathcal{S}_k, \hat{s}_k \in \hat{\mathcal{S}}_k} d_k(s_k, \hat{s}_k) < \infty, \quad k = 1, 2. \quad (47)$$

Our interest is in the two *expected average per-block distortions*

$$\Delta_k^{(n)} := \frac{1}{n} \sum_{i=1}^n \mathbb{E}[d_k(S_{k,i}, \hat{S}_{k,i})], \quad k = 1, 2. \quad (48)$$

and the joint probability of error

$$P_e^{(n)} := \Pr\left(\left(\hat{W}_{0,k}, \hat{W}_1\right) \neq (W_0, W_1) \quad \text{or} \quad \left(\hat{W}_{0,k}, \hat{W}_2\right) \neq (W_0, W_2)\right). \quad (49)$$

Definition 3. A *rate-distortion tuple* $(R_0, R_1, R_2, D_1, D_2)$ is *achievable* if there exists a sequence (in n) of $(2^{nR_0}, 2^{nR_1}, 2^{nR_2}, n)$ codes that simultaneously satisfy

$$\lim_{n \rightarrow \infty} P_e^{(n)} = 0 \quad (50a)$$

$$\overline{\lim}_{n \rightarrow \infty} \Delta_k^{(n)} \leq D_k, \quad \text{for } k = 1, 2. \quad (50b)$$

Definition 4. The *capacity-distortion region* \mathcal{CD} is given by the closure of the union of all achievable rate-distortion tuples $(R_0, R_1, R_2, D_1, D_2)$.

In the remainder of the section, we present bounds on the capacity-distortion region \mathcal{CD} . As in the single-receiver case, one can easily determine the optimal estimator functions h_1 and h_2 , which are independent of the encoding and decoding functions and operate on a symbol-by-symbol basis.

Lemma 3. For each $k = 1, 2$, define the function

$$\hat{s}_k^*(x, z) := \arg \min_{s' \in \hat{\mathcal{S}}_k} \sum_{s_k \in \mathcal{S}_k} P_{S_k | XZ}(s_k | x, z) d(s_k, s'), \quad (51)$$

where ties can be broken arbitrarily.

Irrespective of the choice of encoding and decoding functions, distortions $\Delta_1^{(n)}$ and $\Delta_2^{(n)}$ are minimized by the estimators

$$h_k^*(x^n, z^n) = (\hat{s}_k^*(x_1, z_1), \hat{s}_k^*(x_2, z_2), \dots, \hat{s}_k^*(x_n, z_n)), \quad k = 1, 2. \quad (52)$$

Proof: See Appendix A. ■

Analogously to the definition in equation 8 we can then define the optimal estimation cost for each input symbol $x \in \mathcal{X}$:

$$c_k(x) := \mathbb{E}[d_k(S_k, \hat{s}_k^*(X, Z)) | X = x], \quad k = 1, 2. \quad (53)$$

Characterizing the capacity-distortion region is very challenging in general, because even the capacity regions of the SDMBC with and without feedback are unknown to date. We first present the exact capacity-distortion region for the class of physically degraded SDMBCs and then provide bounds for general SDMBCs. We shall also compare our results on the capacity-distortion regions to the performances achieved by simple TS baseline schemes, in analogy to the single-receiver setup.

Specifically, we again have a *basic TS baseline scheme* that performs either sensing or communication at a time, and an *improved TS baseline scheme* that is able to perform both functions simultaneously via a common waveform by prioritizing either sensing or communication. Analogously to the single-receiver setup, each of the two baseline schemes time-shares between a sensing mode and a communication mode. However, since we now have two distortions and three rates, the choice of the “optimal” pmf P_X for each mode is not necessarily unique, but rather a continuum, depending on which function of the two distortions or the three rates one wishes to optimize. For fixed input pmf, the difference between the communication mode *without sensing* (employed by the basic TS scheme) and the communication mode *with sensing* (employed by the improved TS scheme) lies in the choice of the estimators. In the former mode, the transmitter applies the best *constant estimators* for the two state-sequences, irrespective of its inputs and feedback outputs. In the latter mode, it applies the optimal estimators in Lemma 3, which depend on the input and the feedback output. Similarly, the difference between the communication modes *without and with sensing* is that in the former all rates are zero and in the latter the chosen input pmf P_X can be used for communication at positive rates.

B. Capacity-Distortion Region for Physically Degraded SDMBCs

This section characterizes the capacity-distortion region for *physically degraded SDMBCs* and evaluates it for two binary examples.

Definition 5. An SDMBC $P_{Y_1 Y_2 Z | S_1 S_2 X}$ with state pmf $P_{S_1 S_2}$ is called *physically degraded* if there are conditional laws $P_{Y_1 | X S_1}$ and $P_{S_2 Y_2 | S_1 Y_1}$ such that

$$P_{Y_1 Y_2 | S_1 S_2 X} P_{S_1 S_2} = P_{S_1} P_{Y_1 | S_1 X} P_{S_2 Y_2 | S_1 Y_1}. \quad (54)$$

That means for any arbitrary input P_X , the tuple $(X, S_1, S_2, Y_1, Y_2) \sim P_X P_{S_1 S_2} P_{Y_1 Y_2 | S_1 S_2 X}$ satisfies the Markov chain

$$X \text{---} (S_1, Y_1) \text{---} (S_2, Y_2). \quad (55)$$

Theorem 3. The capacity-distortion region \mathcal{CD} of a physically degraded SDMBC is given by the closure of the set of all tuples $(R_0, R_1, R_2, D_1, D_2)$ for which there exists a joint law P_{UX} so that the tuple $(U, X, S_1, S_2, Y_1, Y_2, Z) \sim P_{UX} P_{S_1 S_2} P_{Y_1 Y_2 Z | S_1 S_2 X}$ satisfies the two rate constraints

$$R_1 \leq I(X; Y_1 | U, S_1) \quad (56)$$

$$R_0 + R_2 \leq I(U; Y_2 | S_2), \quad (57)$$

and the distortion constraints

$$\mathbb{E}[d_k(S_k, \hat{s}_k^*(X, Z))] \leq D_k, \quad k = 1, 2. \quad (58)$$

Proof: The achievability can be proved by standard superposition coding and using the optimal estimators in Lemma 3. The converse also follows from standard steps and the details are provided in Appendix D. ■

In what follows, we evaluate the theorem for two examples.

1) *Example 3: Binary BC with Multiplicative Bernoulli States:* Consider the physically degraded SDMBC with binary input and output alphabets $\mathcal{X} = \mathcal{Y}_1 = \mathcal{Y}_2 = \{0, 1\}$ and binary state alphabets $\mathcal{S}_1 = \mathcal{S}_2 = \{0, 1\}$. The channel input-output relation is described by

$$Y_k = S_k X, \quad k = 1, 2, \quad (59)$$

with the joint state pmf

$$P_{S_1 S_2}(s_1, s_2) = \begin{cases} 1 - q, & \text{if } (s_1, s_2) = (0, 0) \\ 0, & \text{if } (s_1, s_2) = (0, 1) \\ q\gamma, & \text{if } (s_1, s_2) = (1, 1) \\ q(1 - \gamma) & \text{if } (s_1, s_2) = (1, 0), \end{cases} \quad (60)$$

for $\gamma, q \in [0, 1]$. Notice that S_2 is a degraded version of S_1 , which together with the transition law (59) ensures the Markov chain $X \circ - (S_1, Y_1) \circ - (S_2, Y_2)$ and the physically degradedness of the SDMBC. We consider output feedback

$$Z = (Y_1, Y_2), \quad (61)$$

and set the common rate $R_0 = 0$ for simplicity.

In this SDMBC, zero distortions $D_1 = D_2 = 0$ can be achieved by deterministically choosing $X = 1$ exactly as for the single-receiver case. This choice however cannot achieve any positive communication rates, i.e., $R_1 = R_2 = 0$. In the sensing mode with and without communication, we thus have:

$$(R_1, R_2, D_1, D_2) = (0, 0, 0, 0). \quad (62)$$

The optimal input distribution for communication is $X_{\max} \sim \mathcal{B}(1/2)$, in which case all rate-pairs (R_1, R_2) satisfying

$$R_k \leq P_{S_k}(1), \quad k = 1, 2, \quad (63)$$

are achievable. The input $X_{\max} \sim \mathcal{B}(1/2)$ simultaneously maximizes both communication rates R_1, R_2 .

In the communication mode *without* sensing, the transmitter applies the optimal constant estimator for each state, namely

$$\hat{s}_{\text{const},k} := \operatorname{argmax}_{\hat{s} \in \{0,1\}} P_{S_k}(\hat{s}), \quad k = 1, 2, \quad (64)$$

and thus achieves all tuples

$$(R_1, R_2, D_1, D_2) = (qr, \gamma q(1 - r), D_{1,\max}, D_{2,\max}) \quad (65)$$

where $D_{1,\max} := \min\{q, 1 - q\}$ and $D_{2,\max} := \min\{\gamma q, 1 - \gamma q\}$, and $r \in [0, 1]$ denotes the time-sharing parameter between the two communication rates.

In the communication mode *with* sensing, the same input X_{\max} is used. The transmitter however applies the optimal estimator for $k = 1, 2$:

$$\hat{s}_k^*(x, y_1, y_2) = \begin{cases} y_k, & \text{if } x = 1 \\ \hat{s}_{\text{const},k}, & \text{if } x = 0, \end{cases} \quad (66)$$

and achieves the tuple

$$(R_1, R_2, D_1, D_2) = \left(qr, \gamma q(1 - r), \frac{D_{1,\max}}{2}, \frac{D_{2,\max}}{2} \right), \quad (67)$$

where r again denotes the time-sharing parameter between the two communication rates.

The basic and improved TS baseline schemes achieve the time-sharing lines between points (62) and (65) and points (62) and (67), respectively. The following corollary evaluates Theorem 3 to obtain the performance of the optimal co-design scheme.

Corollary 3. *The capacity-distortions region CD of the binary physically degraded SDMBC in (59)–(61) is the set of all tuples $(R_0, R_1, R_2, D_1, D_2)$ satisfying*

$$R_0 + R_1 \leq qH_b(p)r, \quad (68a)$$

$$R_0 + R_2 \leq \gamma qH_b(p)(1 - r), \quad (68b)$$

$$D_1 \geq p \min\{q, 1 - q\}, \quad (68c)$$

$$D_2 \geq p \min\{\gamma q, 1 - \gamma q\}, \quad (68d)$$

for some choice of the parameters $r, p \in [0, 1]$.

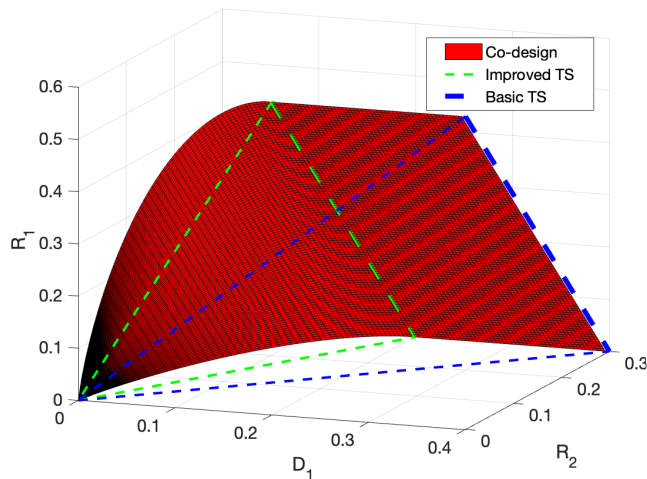

Fig. 5. Boundary of the capacity-distortion region \mathcal{CD} for Example 3 in Subsection III-B1.

Proof: We start by noticing that for this example $I(X; Y_1 | U, S_1) = qH(X|U)$ and $I(U; Y_2 | S_2) = q\gamma(H(X) - H(X | U))$. Setting $p := P_X(0)$ and $r := \frac{H(X|U)}{H(X)}$, directly leads to the desired rate constraints. The distortion constraints are obtained from the optimal estimators in (66). Following the same steps as in the single-receiver case, i.e. (40) and (41), we obtain

$$D_k \geq p \min\{P_{S_k}(0), P_{S_k}(1)\}, \quad (69)$$

which concludes the proof. \blacksquare

Notice that above Corollary 3 reduces to Corollary 2 in the special case of $R_0 = R_2 = 0$ and $D_2 = \infty$, i.e., when we ignore Receiver 2.

Fig. 5 shows in red colour the boundary of the projection of the tradeoff region \mathcal{CD} of this example onto the 3-dimensional plane (R_1, R_2, D_1) , for parameters $\gamma = 0.5$ and $q = 0.6$. The tradeoff with D_2 is omitted for simplicity and because D_2 is a scaled version of D_1 . The figure also shows the boundaries of the basic and improved TS baseline schemes. We again notice a significant gain for an optimal co-design scheme compared to the TS baseline schemes.

So far, there was no tradeoff between the two distortion constraints D_1 and D_2 . This is different in the next example, which otherwise is very similar.

2) *Example 4: Binary BC with Multiplicative Bernoulli States and Flipping Inputs:* Reconsider the same state pmf P_{S_1, S_2} as in the previous example, but now an SDMBC with a transition law that flips the input for receiver 2:

$$Y_1 = S_1 X, \quad Y_2 = S_2 (1 - X). \quad (70)$$

As in the previous example we consider output feedback $Z = (Y_1, Y_2)$.

Corollary 4. *The capacity-distortion region \mathcal{CD} of the binary SDMBC with flipping inputs in (70) and output feedback is the set of all tuples $(R_0, R_1, R_2, D_1, D_2)$ satisfying*

$$R_1 \leq qH_b(p)r, \quad (71a)$$

$$R_0 + R_2 \leq \gamma qH_b(p)(1 - r), \quad (71b)$$

$$D_1 \geq p \min\{q(1 - \gamma), (1 - q)\}, \quad (71c)$$

$$D_2 \geq (1 - p)q \min\{\gamma, 1 - \gamma\}, \quad (71d)$$

for some choice of the parameters $r, p \in [0, 1]$.

The capacity-distortion region expression above captures the tradeoffs between the two rates through the parameter r , between the rates and the distortions through the parameter p , and between the two distortions through the parameter p .

Comparing above Corollary 4 to the previous Corollary 3, we remark the identical rate constraints and the relaxed distortion constraints for both D_1 and D_2 in Corollary 4. The reason is that the flipping input allows the transmitter to perfectly estimate S_1 from (X, Y_1, Y_2) not only when $X = 1$ but also when $X = 0$ and $Y_2 = 1$ because they imply that $S_2 = 1$ and by (60) also $S_1 = 1$.

Proof: The proof is similar to the proof of Corollary 3, except for the description of the optimal estimators. To determine these optimal estimators, we remark that only four input-output relations are possible: $(x, y_1, y_2) \in \{(0, 0, 0), (0, 0, 1), (1, 0, 0), (1, 1, 0)\}$. Moreover, when $X = 1$, then $Y_1 = S_1$, and when $X = 0$, then $Y_2 = S_2$. In particular, when $X = 0$ and $Y_2 = 1$, then $S_2 = 1$ and also $S_1 = 1$, see (60). The optimal estimator for state S_1 thus is:

$$\hat{s}_1^*(x, y_1, y_2) = \begin{cases} y_1, & \text{if } x = 1 \\ 1, & \text{if } (x, y_2) = (0, 1) \\ \arg \min_s P_{S_1|S_2}(s|0), & \text{else,} \end{cases} \quad (72)$$

and $\hat{s}_1^*(X, Y_1, Y_2) = S_1$ unless $X = 0$, $Y_2 = 0$, and $S_1 \neq \arg \min_s P_{S_1|S_2}(s|0)$, which is equivalent to $(X = 0, S_2 = 0)$ and $S_1 \neq \arg \min_s P_{S_1|S_2}(s|0)$. This yields $c_1(1) = 0$ and because S_2 is independent of X :

$$c_1(0) = P_{S_2}(0) \min_s P_{S_1|S_2}(s|0). \quad (73)$$

Recalling $p = P_X(0)$, we readily obtain the distortion for state S_1 :

$$D_1 = p \min_s P_{S_1, S_2}(s, 0) = p \min\{q(1 - \gamma), 1 - q\}. \quad (74)$$

The optimal estimator and the corresponding distortion for state S_2 can be obtained in a similar way. ■

C. Capacity-Distortion Region for General SDMBCs

In the remainder of this section, we reconsider general SDMBCs, for which we present bounds on \mathcal{CD} . We start with a simple outer bound.

Theorem 4 (Outer Bound on \mathcal{CD}). *If $(R_0, R_1, R_2, D_1, D_2)$ lies in \mathcal{CD} for a given SDMBC $P_{Y_1 Y_2 Z | S_1 S_2 X}$ with state pmf $P_{S_1 S_2}$, then there exists for each $k = 1, 2$ a conditional pmf $P_{U_k | X}$ such that the random tuple $(U_k, X, S_1, S_2, Y_1, Y_2, Z) \sim P_{U_k | X} P_X P_{S_1 S_2} P_{Y_1 Y_2 Z | S_1 S_2 X}$ satisfies the rate constraints*

$$R_0 + R_k \leq I(U_k; Y_k | S_k), \quad k = 1, 2, \quad (75a)$$

$$R_0 + R_1 + R_2 \leq I(X; Y_1, Y_2 | S_1, S_2), \quad (75b)$$

and the average distortion constraint

$$\mathbb{E}[d_k(S_k, \hat{s}_k^*(X, Z))] \leq D_k, \quad k = 1, 2, \quad (76)$$

where the function $\hat{s}_k^*(\cdot, \cdot)$ is defined in (51).

Proof: See Appendix D. ■

Achievability results are easily obtained by combining existing achievability results for SDMBCs with generalized feedback with the optimal estimator in Lemma 3. For example, based on [16] we obtain:

Proposition 1 (Inner Bound on \mathcal{CD}). *Consider an SDMBC $P_{Y_1 Y_2 Z | S_1 S_2 X}$ with state pmf $P_{S_1 S_2}$. The capacity-distortion region \mathcal{CD} includes all tuples $(R_0, R_1, R_2, D_1, D_2)$ that satisfy inequalities (77) on top of this page and the distortion constraints (76). where $(U_0, U_1, U_2, X, S_1, S_2, Y_1, Y_2, Z, V_0, V_1, V_2) \sim P_{U_0 U_1 U_2 X} P_{S_1 S_2} P_{Y_1 Y_2 Z | S_1 S_2 X} P_{V_0 V_1 V_2 | U_0 U_1 U_2 Z}$, for some choice of (conditional) pmfs $P_{U_0 U_1 U_2 X}$ and $P_{V_0 V_1 V_2 | U_0 U_1 U_2 Z}$.*

Proof: Similar to [16] and omitted. ■

In analogy to Corollary 1 for the single-receiver case, for some SDMBCs there is no tradeoff between the achievable distortions and communication rates. In this case, for the BC, the capacity-distortion region is given by the Cartesian product between the SDMBC's capacity region:

$$\mathcal{C} := \{(R_0, R_1, R_2) : D_1 \geq 0, D_2 \geq 0 \quad \text{s.t. } (R_0, R_1, R_2, D_1, D_2) \in \mathcal{CD}\}, \quad (78)$$

$$R_0 + R_1 \leq I(U_0, U_1; Y_1, V_1 | S_1) - I(U_0, U_1, U_2, Z; V_0, V_1 | S_1, Y_1) \quad (77a)$$

$$R_0 + R_2 \leq I(U_0, U_2; Y_2, V_2 | S_2) - I(U_0, U_1, U_2, Z; V_0, V_2 | S_2, Y_2) \quad (77b)$$

$$\begin{aligned} R_0 + R_1 + R_2 &\leq I(U_1; Y_1, V_1 | U_0, S_1) + I(U_2; Y_2, V_2 | U_0, S_2) + \min_{k \in \{1,2\}} I(U_0; Y_k, V_k | S_k) - I(U_1; U_2 | U_0) \\ &\quad - I(U_0, U_1, U_2, Z; V_1 | V_0, S_1, Y_1) - I(U_0, U_1, U_2, Z; V_2 | V_0, S_2, Y_2) \\ &\quad - \max_{k \in \{1,2\}} I(U_0, U_1, U_2, Z; V_0 | S_k, Y_k) \end{aligned} \quad (77c)$$

$$\begin{aligned} 2R_0 + R_1 + R_2 &\leq I(U_0, U_1; Y_1, V_1 | S_1) + I(U_0, U_2; Y_2, V_2 | S_2) - I(U_1; U_2 | U_0) \\ &\quad - I(U_0, U_1, U_2, Z; V_0, V_1 | S_1, Y_1) - I(U_0, U_1, U_2, Z; V_0, V_2 | S_2, Y_2) \end{aligned} \quad (77d)$$

and its distortion region:

$$\mathcal{D} := \{(D_1, D_2) : R_0 \geq 0, R_1 \geq 0, R_2 \geq 0 \quad \text{s.t.} \quad (R_0, R_1, R_2, D_1, D_2) \in \mathcal{CD}\}. \quad (79)$$

Proposition 2 (No Rate-Distortion Tradeoff). *Consider an SDMBC $P_{Y_1 Y_2 Z | S_1 S_2 X}$ with state pmf $P_{S_1 S_2}$ for which there exist functions ψ_1 and ψ_2 with domain $\mathcal{X} \times \mathcal{Z}$ so that irrespective of the input distribution P_X the relations*

$$(S_k, \psi_k(Z, X)) \perp X, \quad (80)$$

$$S_k \text{---} \psi_k(Z, X) \text{---} (Z, X), \quad k = 1, 2, \quad (81)$$

hold for $(S_1, S_2, X_2 Z) \sim P_{S_1} P_{S_2} P_X P_{Z | X S_1, X_2}$. The capacity-distortion region of this SDMBC is the product of the capacity region and the distortion region:

$$\mathcal{CD} = \mathcal{C} \times \mathcal{D}. \quad (82)$$

Proof: Analogous to the proof of Corollary 1. Specifically, the proof is obtained from Appendix C by replacing (S, \hat{S}, ψ, Y, T) with $(S_k, \hat{S}_k, \psi_k, Y_k, T_k)$, for $k = 1, 2$. ■

D. Example 5: Erasure BC with Noisy Feedback

Our first example satisfies Conditions (80) and (81) in Proposition 2 for an appropriate choice of ψ_1 and ψ_2 , and its capacity-distortion region is thus given by the product of the capacity region and the distortion region.

Let $(E_1, S_1, E_2, S_2) \sim P_{E_1 S_1 E_2 S_2}$ over $\{0, 1\}^4$ be given but arbitrary. Consider the state-dependent erasure BC

$$Y_k = \begin{cases} X & \text{if } S_k = 0, \\ ? & \text{if } S_k = 1, \end{cases}, \quad k = 1, 2, \quad (83)$$

where the feedback signal $Z = (Z_1, Z_2)$ is given by

$$Z_k = \begin{cases} Y_k & \text{if } E_k = 0, \\ ? & \text{if } E_k = 1, \end{cases}, \quad k = 1, 2. \quad (84)$$

Further consider Hamming distortion measures $d_k(s, \hat{s}) = s \oplus \hat{s}$, for $k = 1, 2$. For the choice

$$\psi_k(Z_k) = \begin{cases} 1, & \text{if } Z_k = ?, \\ 0, & \text{else,} \end{cases} \quad (85)$$

the described SDMBC satisfies the conditions in Proposition 2, thus yielding the following corollary.

Corollary 5. *The capacity-distortion region of the state-dependent erasure BC with noisy feedback in (83)–(84) is the Cartesian product between the capacity region of the SDMBC and its distortion region:*

$$\mathcal{CD} = \mathcal{C} \times \mathcal{D}. \quad (86)$$

When $P_{E_1 S_1 E_2 S_2} = P_{E_1 S_1} P_{E_2 S_2}$, then the distortion region is given by:

$$\mathcal{D} = \{(D_1, D_2) : D_k \geq P_{E_k S_k}(1, 0)\}. \quad (87)$$

Fig. 6. State-dependent Dueck Broadcast Channel.

The capacity region \mathcal{C} of this SDMBC is unknown even with perfect feedback.¹

Proof. The state can perfectly be estimated ($S_k = 0$) with zero distortion if $(S_k, E_k) = (0, 0)$. Otherwise, the feedback is $Z_k = ?$ and provides no information. The optimal estimator is then given by the best constant estimator, which in this example is:

$$\hat{s}_{\text{const},k} = \mathbf{1}\{P_{S_k}(1) \geq P_{S_k E_k}(0, 1)\}. \quad (88)$$

This immediately yields the distortion constraint in (87). \square

E. Example 6: State-Dependent Dueck's BC with Multiplicative Bernoulli States

Consider the state-dependent version of Dueck's BC [25] in Figure 6 with input $X = (X_0, X_1, X_2) \in \{0, 1\}^3$, i.i.d. Bernoulli states $S_1, S_2 \sim \mathcal{B}(q)$, for $q \in [0, 1]$, and outputs

$$Y_k = (X_0, Y'_k, S_1, S_2), \quad k = 1, 2, \quad (89)$$

where

$$Y'_k = S_k(X_k \oplus N), \quad k = 1, 2, \quad (90a)$$

and the noise $N \sim \mathcal{B}(1/2)$ is independent of the inputs and the states. The feedback signal is

$$Z = (Y'_1, Y'_2), \quad (91)$$

and for simplicity we again ignore the common rate R_0 .

We notice that only X_1 and X_2 are corrupted by the state and the noise. Since X_0 is received without any state or noise, it is thus completely useless for sensing. In fact, the optimal estimator of Lemma 3 is (see Appendix F-A)

$$\hat{s}_k^*(x_1, x_2, y'_1, y'_2) = \begin{cases} 1 & y'_k = 1 \\ 0 & y'_k = 0, y'_k = 1, x_1 = x_2 \\ \mathbb{1}\{q \geq (1-q)\} & y'_k = 0, y'_k = 1, x_1 \neq x_2, \\ 0 & y_1 = y_2 = 0, x_1 \neq x_2 \\ \mathbb{1}\{q \geq (1-q)(2-q)\} & y'_1 = y'_2 = 0, x_1 = x_2 \end{cases} \quad k = 1, 2, \quad (92)$$

where we slightly abuse notation by omitting the argument x_0 for the estimator \hat{s}_k^* because this latter does not depend on x_0 .

For a given input pmf with probability $t := \Pr[X_1 \neq X_2]$, the expected distortion achieved by the optimal estimators in (92) is (see Appendix F-B):

$$\begin{aligned} & \mathbb{E}[d_k(S_k, \hat{s}_k^*(X_1, X_2, Y'_1, Y'_2))] \\ &= \frac{1}{2}tq(\min\{q, 1-q\} + (1-q)) + \frac{1}{2}(1-t)\min\{q, (1-q)(2-q)\} \end{aligned} \quad (93)$$

¹In [23], [24], the capacity region of the erasure BC with output feedback has been characterized when each receiver is informed about the state realizations of both receivers.

We observe different cases: i) for $q \in [0, 1/2]$, both minima are achieved by q ; ii) for $q \in (1/2, 2 - \sqrt{2}]$, the first and second minima are achieved by $1 - q$ and q , respectively; iii) for $q \in (2 - \sqrt{2}, 1]$, the first and second minimum are achieved by $(1 - q)$ and $(1 - q)(2 - q)$, respectively. The distortion constraint (76) thus evaluates to:

$$D_k \geq \begin{cases} q/2 & q \in [0, 1/2] \\ q(1 - t(2q - 1))/2 & q \in (1/2, 2 - \sqrt{2}] \\ (1 - q)(2 - q + t(3q - 2))/2 & q \in (2 - \sqrt{2}, 1]. \end{cases} \quad (94)$$

We notice that for $q \in [0, 1/2]$, the distortion constraint is independent of t and thus of P_X , and the minimum expected distortions are $D_{\min,1} = D_{\min,2} = \frac{1}{2}q$. For $q \in (1/2, 2 - \sqrt{2}]$, the minimum expected distortions are achieved for $t = 1$ and the same holds also for $q \in (2 - \sqrt{2}, 2/3]$. For $q \in [2/3, 1]$, the distortions are minimized for $t = 0$. We thus have $D_{\min,1} = D_{\min,2} = D_{\min}$, where

$$D_{\min} := \begin{cases} q/2, & q \in [0, 1/2] \\ q(1 - q), & q \in [1/2, 2/3] \\ (1 - q)(2 - q)/2, & q \in [2/3, 1]. \end{cases} \quad (95)$$

We obtain a characterization of the distortion region:

$$\mathcal{D} = \{(D_1, D_2) : D_1 \geq D_{\min}, D_2 \geq D_{\min}\}. \quad (96)$$

The private-messages capacity region is:

$$\mathcal{C} = \{(R_1, R_2) : R_1 \leq 1, R_2 \leq 1, \text{ and } R_1 + R_2 \leq 1 + q^2\}. \quad (97)$$

The converse and achievability proofs are provided in Appendices F-C and F-D, respectively.

Reconsider now the case where $q \in [0, 1/2]$. As previously explained, the distortion is independent of the input distribution, and the capacity-distortion region \mathcal{CD} degenerates to the product of the capacity and distortion regions:

Corollary 6 (No Rate-Distortion Tradeoff). *For above state-dependent Dueck example with $q \in [0, 1/2]$:*

$$\mathcal{CD} = \mathcal{C} \times \mathcal{D}. \quad (98)$$

For the general case, we only have bounds on the capacity-distortion region \mathcal{CD} . We first present our outer bound, which is based on Theorem 4 and proved in Appendix F-C.

Corollary 7 (Outer Bound). *The capacity-distortion region \mathcal{CD} (without common message) of Dueck's state-dependent BC is included in the set of tuples (R_1, R_2, D_1, D_2) that for some choice of the parameters $t \in [0, 1]$ satisfy the rate-constraints*

$$R_k \leq 1, \quad k = 1, 2, \quad (99)$$

$$R_1 + R_2 \leq 1 + q^2 H_b(t) \quad (100)$$

and the distortion constraints in (94).

The inner bound is based on Proposition 1, see Appendix F-D. Together with the outer bound in Corollary 7 it characterizes both the distortion region \mathcal{D} and the capacity region \mathcal{C} in (96) and (97).

Corollary 8 (Inner bound). *The capacity-distortion region \mathcal{CD} of the state-dependent Dueck BC includes all rate-distortion tuples (R_1, R_2, D_1, D_2) that for some choice of $t \in [0, 1]$ satisfy (94) and*

$$R_k \leq 1, \quad k = 1, 2, \quad (101)$$

$$R_1 + R_2 \leq 1 + qH_b(t) - q(1 - q), \quad (102)$$

as well as the convex hull of all these tuples.

Fig. 7 shows our outer and inner bounds in Corollaries 7 and 8 for $q = 3/4$, where in the inner bound we consider the convex hull operation through convex combinations between values of $t > 0$ and $t = 0$. The figure also shows the performances of the basic and improved TS baseline schemes, whose modes we explain next. (Recall that

the basic TS scheme time-shares the sensing mode without communication and the communication mode without sensing, and the improved TS scheme time-shares the sensing mode with communication and the communication mode with sensing.)

Sensing mode with and without communication:

In the sensing mode with communication, one can choose an arbitrary pmf for X_0 , e.g., X_0 Bernoulli-1/2 because this input does not affect the sensing. From (95), the minimum distortions of $D_{\min,1} = D_{\min,2} = 5/32$ are achieved by setting $X_1 = X_2$ with probability 1. For $X_1 = X_2$ the sum-rate cannot exceed $R_1 + R_2 \leq 1$, because $I(X_0, X_1, X_2; Y_1, Y_2) = I(X_0, X_2; Y_1, Y_2) \leq H(X_0) + I(X_2; Y'_1, Y'_2|X_0) \leq 1$ as Y'_1 and Y'_2 are corrupted by the Bernoulli-1/2 noise N . On the other hand, any rate pair (R_1, R_2) of sum-rate $R_1 + R_2 = 1$ is trivially achievable by communicating only with the noiseless X_0 -input.

We conclude that the sensing mode with communication achieves the rate-distortion tuple (R_1, R_1, D_1, D_2) satisfying

$$R_1 + R_2 \leq 1 \quad \text{and} \quad D_k \geq 5/32, \quad k = 1, 2. \quad (103)$$

If the transmitter cannot perform communication and sensing tasks simultaneously, the same minimum distortions are achieved but the rates are trivially zero.

$$R_1 + R_2 = 0 \quad \text{and} \quad D_k \geq 5/32, \quad k = 1, 2. \quad (104)$$

Communication mode with and without sensing:

The optimal pmf P_X achieving the capacity region in (97) corresponds to i.i.d. Bernoulli-1/2 distributed X_0, X_1, X_2 (Appendix F-D). The corresponding sum rate is $R_1 + R_2 = 1 + q^2 = 25/16$. The minimum achievable distortions are thus obtained from (94) by setting $t = \Pr[X_1 \neq X_2] = 1/2$, i.e., $D_{\max,1} = D_{\max,2} = 11/64$. The best constant estimator is $\hat{S}_1 = \hat{S}_2 = 1$ because $3/4 = P_{S_k}(1) > P_{S_k}(0) = 1/4$, which achieves distortions $D_{\text{trivial},1} = D_{\text{trivial},2} = 1/4$. We can conclude that the communication mode with sensing achieves all rate-distortion tuples (R_1, R_1, D_1, D_2) satisfying

$$R_k \leq 1 \quad \text{and} \quad R_1 + R_2 \leq 25/16 \quad \text{and} \quad D_k \geq 11/64, \quad k = 1, 2 \quad (105)$$

and the communication mode without sensing achieves all rate-distortion tuples (R_1, R_1, D_1, D_2) satisfying

$$R_k \leq 1 \quad \text{and} \quad R_1 + R_2 \leq 25/16 \quad \text{and} \quad D_k \geq 1/4, \quad k = 1, 2. \quad (106)$$

Fig. 7. Sum-rate $R_1 + R_2$ vs. symmetric distortion $D_1 = D_2$ for the state-dependent Dueck BC with $q = 3/4$.

IV. CONCLUSION

Motivated by the paradigm of integrated sensing and communication systems, we studied joint sensing and communication in memoryless state-dependent channels. We fully characterized the capacity-distortion tradeoff for the single-user channels as well as physically-degraded broadcast channels. For general broadcast channels, we presented inner and outer bounds on the capacity-distortion region. Through a number of illustrative examples, we demonstrated that the optimal co-design scheme offers non-negligible gain compared to the basic time-sharing scheme that performs either sensing or communication, as well as compared to the improved time-sharing scheme that *prioritizes* one of these two tasks. Interestingly, there are ideal situations where the capacity is achieved without compromising the sensing performance. While for memoryless channels, the absence of a tradeoff appears to be rather exceptional, we expect that this situation will be more common for channels with memory. This is because for temporally correlated channels, a good state estimation at the transmitter not only yields good sensing performance but is also beneficial for communication. In fact, in some preliminary examples that we considered, we can achieve rate-distortion points that are close to the ideal point where rate equals capacity and distortion is minimal. The capacity-distortion tradeoff characterization for channels with memory remains as an interesting future work.

ACKNOWLEDGEMENTS

The authors would like to thank Gerhard Kramer for his support on an early version of this paper.

APPENDIX A PROOF OF LEMMA 1

Recall that $\hat{S}^n = h(X^n, Z^n)$, and write for each $i = 1, \dots, n$:

$$\mathbb{E} \left[d(S_i, \hat{S}_i) \right] = \mathbb{E}_{X^n, Z^n} \left[\mathbb{E}[d(S_i, \hat{S}_i) | X^n, Z^n] \right] \quad (107)$$

$$\stackrel{(a)}{=} \sum_{x^n, z^n} P_{X^n Z^n}(x^n, z^n) \sum_{\hat{s} \in \mathcal{S}} P_{\hat{S}_i | X^n Z^n}(\hat{s} | x^n, z^n) \sum_s P_{S_i | X_i Z_i}(s | x_i, z_i) d(s, \hat{s}) \quad (108)$$

$$\geq \sum_{x^n, z^n} P_{X^n Z^n}(x^n, z^n) \min_{\hat{s} \in \mathcal{S}} \sum_s P_{S_i | X_i Z_i}(s | x_i, z_i) d(s, \hat{s}) \quad (109)$$

$$= \mathbb{E}[d(S_i, \hat{s}^*(X_i, Z_i))], \quad (110)$$

where (a) holds by the Markov chain

$$\left(X^{i-1}, X_{i+1}^n, Z^{i-1}, Z_{i+1}^n, \hat{S}_i \right) \text{---} (X_i, Z_i) \text{---} S_i. \quad (111)$$

Summing over all $i = 1, \dots, n$, we thus obtain:

$$\Delta^{(n)} = \frac{1}{n} \sum_{i=1}^n \mathbb{E} \left[d(S_i, \hat{S}_i) \right] \quad (112)$$

$$\geq \frac{1}{n} \sum_{i=1}^n \mathbb{E}[d(S_i, \hat{s}^*(X_i, Z_i))], \quad (113)$$

which yields the desired conclusion.

APPENDIX B
PROOF OF THEOREM 1

1) *Converse*: Fix a sequence (in n) of $(2^{nR}, n)$ codes such that Limits (4) hold. By Fano's inequality there exists a sequence $\epsilon_n \rightarrow 0$ as $n \rightarrow \infty$ so that:

$$\begin{aligned}
nR &\leq I(W; Y^n, S^n) + n\epsilon_n \\
&= I(W; Y^n | S^n) + n\epsilon_n \\
&= \sum_{i=1}^n H(Y_i | Y^{i-1} S^n) - H(Y_i | W, Y^{i-1} S^n) + n\epsilon_n \\
&\stackrel{(a)}{\leq} \sum_{i=1}^n H(Y_i | S_i) - H(Y_i | X_i, Y^{i-1}, W, S^n) + n\epsilon_n \\
&\stackrel{(b)}{=} \sum_{i=1}^n H(Y_i | S_i) - H(Y_i | X_i, S_i) + n\epsilon_n \\
&= \sum_{i=1}^n I(X_i; Y_i | S_i) + n\epsilon_n
\end{aligned} \tag{114}$$

where (a) holds because conditioning can only reduce entropy; and (b) holds because $(W, Y^{i-1}, S^{i-1}, S_{i+1}^n) - (S_i, X_i) - Y_i$ form a Markov chain. We continue as:

$$\begin{aligned}
R &\leq \frac{1}{n} \sum_{i=1}^n I(X_i; Y_i | S_i) + \epsilon_n \\
&\stackrel{(c)}{\leq} \frac{1}{n} \sum_{i=1}^n C_{\text{inf}} \left(\sum_x P_{X_i}(x) c(x), \sum_x P_{X_i}(x) b(x) \right) + \epsilon_n \\
&\stackrel{(d)}{\leq} C_{\text{inf}} \left(\frac{1}{n} \sum_{i=1}^n \sum_x P_{X_i}(x) c(x), \frac{1}{n} \sum_{i=1}^n \sum_x P_{X_i}(x) b(x) \right) + \epsilon_n \\
&\stackrel{(e)}{\leq} C_{\text{inf}}(\text{D}, \text{B})
\end{aligned} \tag{115}$$

where (c) holds by the definition of $C_{\text{inf}}(\text{D}, \text{B})$, and (d) and (e) hold by Lemma 2.

2) *Achievability*: Fix $P_X(\cdot)$ and functions $\hat{h}(x, z)$ that achieve $C(\text{D}/(1+\epsilon), \text{B})$, where D is the desired distortion and B is the target cost, for a small positive number $\epsilon > 0$. We define the joint pmf $P_{SXY} := P_S P_X P_{Y|SX}$.

a) *Codebook generation*: Generate 2^{nR} sequences $\{x^n(w)\}_{w=1}^{2^{nR}}$ by randomly and independently drawing each entry according to P_X . This defines the codebook $\mathcal{C} = \{x^n(w)\}_{w=1}^{2^{nR}}$, which is revealed to the encoder and the decoder.

b) *Encoding*: To send a message $w \in \mathcal{W}$, the encoder transmits $x^n(w)$.

c) *Decoding*: Upon observing outputs $Y^n = y^n$ and state sequence $S^n = s^n$, the decoder looks for an index \hat{w} such that

$$(s^n, x^n(\hat{w}), y^n) \in \mathcal{T}_\epsilon^{(n)}(P_{SXY}). \tag{116}$$

If exactly one such index exists, it declares $\hat{W} = \hat{w}$. Otherwise, it declares an error.

d) *Estimation*: Assuming that it sent the input sequence $X^n = x^n$ and observed the feedback signal $Z^n = z^n$, the encoder computes the reconstruction sequence as:

$$\hat{S}^n = (\hat{s}^*(x_1, z_1), \hat{s}^*(x_2, z_2), \dots, \hat{s}^*(x_n, z_n)). \tag{117}$$

e) *Analysis*: We start by analyzing the probability of error and the distortion averaged over the random code construction. Given the symmetry of the code construction, we can condition on the event $W = 1$.

We then notice that the decoder makes an error, i.e., declares nothing or $\hat{W} \neq 1$ if, and only if, one or both of the following events occur:

$$\mathcal{E}_1 = \{(S^n, X^n(1), Y^n) \notin \mathcal{T}_\epsilon^{(n)}(P_S P_X P_{Y|SX})\} \tag{118}$$

$$\mathcal{E}_2 = \{(S^n, X^n(w'), Y^n) \in \mathcal{T}_\epsilon^{(n)}(P_S P_X P_{Y|S_X}) \text{ for some } w' \neq 1\}. \quad (119)$$

Thus, by the union bound:

$$P_e^{(n)} = P(\mathcal{E}_1 \cup \mathcal{E}_2) \leq P(\mathcal{E}_1) + P(\mathcal{E}_2). \quad (120)$$

The first term goes to zero as $n \rightarrow \infty$ by the weak law of large numbers. The second term also tends to zero as $n \rightarrow \infty$ if $R < I(X; Y|S)$ by the independence of the codewords and the packing lemma [19, Lemma 3.1]. Therefore, $P_e^{(n)}$ tends to zero as $n \rightarrow \infty$ whenever $R < I(X; Y|S)$.

The expected distortion (averaged over the random codebook, state and channel noise) can be upper bounded as

$$\Delta^{(n)} = \frac{1}{n} \sum_{i=1}^n \mathbb{E} \left[d(S_i, \hat{S}_i) \right] \quad (121)$$

$$= \frac{1}{n} \sum_{i=1}^n \mathbb{E} \left[d(S_i, \hat{S}_i) | \hat{W} \neq 1 \right] \Pr(\hat{W} \neq 1) + \frac{1}{n} \sum_{i=1}^n \mathbb{E} \left[d(S_i, \hat{S}_i) | \hat{W} = 1 \right] \Pr(\hat{W} = 1) \quad (122)$$

$$\leq D_{\max} P_e + \frac{1}{n} \sum_{i=1}^n \mathbb{E} \left[d(S_i, \hat{S}_i) | \hat{W} = 1 \right] (1 - P_e). \quad (123)$$

In the event of correct decoding, i.e., $\hat{W} = 1$,

$$(S^n, X^n(1), Y^n) \in \mathcal{T}_\epsilon^{(n)}(P_S P_X P_{Y|S_X}), \quad (124)$$

and since $\hat{S}_i = \hat{s}^*(X_i, Z_i)$, also

$$(S^n, X^n(1), \hat{S}^n) \in \mathcal{T}_\epsilon^{(n)}(P_{S_X \hat{S}}), \quad (125)$$

where $P_{S_X \hat{S}}$ denotes the joint marginal pmf of $P_{S_X Z \hat{S}}(s, x, z, \hat{s}) := P_S(s) P_X(x) P_{Z|S_X}(z|s, x) \mathbb{1}\{\hat{s} = \hat{s}^*(x, z)\}$. Then,

$$\overline{\lim}_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \mathbb{E} \left[d(S_i, \hat{S}_i) | \hat{W} = 1 \right] \leq (1 + \epsilon) \mathbb{E} \left[d(S, \hat{S}) \right], \quad (126)$$

for (S, \hat{S}) following the marginal of the pmf $P_{S_X Z \hat{S}}$ defined above. Assuming that $R < I(X; Y|S)$, and thus $P_e \rightarrow 0$ as $n \rightarrow \infty$, we obtain from (123) and (126):

$$\overline{\lim}_{n \rightarrow \infty} \Delta^{(n)} = (1 + \epsilon) \mathbb{E} \left[d(S, \hat{S}) \right]. \quad (127)$$

Taking finally $\epsilon \downarrow 0$, we can conclude that the error probability and distortion constraint (4a), (4b) hold (averaged over the random code constructions, the random states, and the noise in the channel) whenever

$$R < I(X; Y | S), \quad (128)$$

$$\mathbb{E} \left[d(S, \hat{S}) \right] < D. \quad (129)$$

Notice that the cost constraint (4c) is fulfilled by construction. By standard arguments it can then be shown that there must exist at least one sequence of deterministic code books \mathcal{C}_n so that constraints (4) hold.

APPENDIX C
PROOF OF COROLLARY 1

It suffices to show that under the described conditions, the distortion constraint (4b) does not depend on P_X . To this end, we define $T = \psi(X, Z)$ and rewrite the expected distortion as:

$$\mathbb{E}[d(S, \hat{S})] = \sum_{(x,z) \in \mathcal{X} \times \mathcal{Z}} P_{XZ}(x, z) \sum_{s \in \mathcal{S}} P_{S|XZ}(s | x, z) d(s, \hat{s}^*(x, z)) \quad (130)$$

$$\stackrel{(a)}{=} \sum_{(x,z) \in \mathcal{X} \times \mathcal{Z}} P_{XZ}(x, z) \min_{s' \in \hat{\mathcal{S}}} \sum_{(s,t) \in \mathcal{S} \times \mathcal{T}} P_{ST|XZ}(s, t | x, z) d(s, s') \quad (131)$$

$$\stackrel{(b)}{=} \sum_{(x,z,t) \in \mathcal{X} \times \mathcal{Z} \times \mathcal{T}} P_{XZ}(x, z) \mathbb{1}\{t = \psi(x, z)\} \min_{s' \in \hat{\mathcal{S}}} \sum_{s \in \mathcal{S}} P_{S|T}(s | t) d(s, s') \quad (132)$$

$$= \sum_{t \in \mathcal{T}} P_T(t) \min_{s' \in \hat{\mathcal{S}}} \sum_{s \in \mathcal{S}} P_{S|T}(s | t) d(s, s') \quad (133)$$

where (a) holds by the definition of $\hat{s}^*(x, z)$ and the law of total probability; and (b) by the Markov chain $S \circ - T \circ - (X, Z)$, see (17), and because T is a function of X, Z . The independence of the pair (T, S) with X from (16), together with the above expression implies that the expected distortion does not depend on the choice of the input distribution P_X . Hence, we can conclude that for any given $B \geq 0$, the rate-distortion tradeoff function $C(D, B)$ is constant over all $D \geq D_{\min}$ and coincides with the capacity of the SDMC $C_{\text{NoEst}}(B)$.

APPENDIX D
CONVERSE PROOF OF THEOREM 3

Fix a sequence (in n) of $(2^{nR_0}, 2^{nR_1}, 2^{nR_2}, n)$ codes satisfying (50). Fix a blocklength n and start with Fano's inequality:

$$\begin{aligned} R_0 + R_2 &= \frac{1}{n} H(W_0, W_2) \\ &\leq \frac{1}{n} \sum_{i=1}^n I(W_0, W_2; Y_{2,i}, S_{2,i} | Y_2^{i-1}, S_2^{i-1}) + \epsilon_n \\ &\leq \frac{1}{n} \sum_{i=1}^n I(W_0, W_2, Y_2^{i-1}, S_2^{i-1}; Y_{2,i}, S_{2,i}) + \epsilon_n \\ &= I(W_0, W_2, Y_2^{T-1}, S_2^{T-1}; Y_{2,T}, S_{2,T} | T) + \epsilon_n \\ &\leq I(W_0, W_2, Y_2^{T-1}, S_2^{T-1}, T; Y_{2,T}, S_{2,T}) + \epsilon_n \\ &\stackrel{(a)}{=} I(U; Y_2 | S_2) + \epsilon_n, \end{aligned} \quad (134)$$

where T is chosen uniformly over $\{1, \dots, n\}$ and independent of $X^n, Y_1^n, Y_2^n, W_0, W_1, W_2, S_1^n, S_2^n$; ϵ_n is a sequence that tends to 0 as $n \rightarrow \infty$; and $U := (W_0, W_2, Y_2^{T-1}, S_2^{T-1}, T)$, $Y_2 := Y_{2,T}$ and $S_2 := S_{2,T}$. Here (a) holds because $S_2 \sim P_{S_2}$ independent of (U, X) , where we define $X := X_T$.

Following similar steps, we obtain:

$$\begin{aligned} R_1 &= \frac{1}{n} H(W_1 | W_0, W_2) \\ &\leq \frac{1}{n} I(W_1; Y_1^n, S_1^n | W_0, W_2) + \epsilon_n \\ &\leq \frac{1}{n} I(W_1; Y_1^n, S_1^n, Y_2^n, S_2^n | W_0, W_2) + \epsilon_n \\ &= \frac{1}{n} \sum_{i=1}^n I(W_1; Y_{1,i}, Y_{2,i}, S_{1,i}, S_{2,i} | Y_1^{i-1}, Y_2^{i-1}, S_1^{i-1}, S_2^{i-1}, W_0, W_2) + \epsilon_n \\ &\leq \frac{1}{n} \sum_{i=1}^n I(X_i, W_1, Y_1^{i-1}, S_1^{i-1}; Y_{1,i}, Y_{2,i}, S_{1,i}, S_{2,i} | Y_2^{i-1}, S_2^{i-1}, W_0, W_2) + \epsilon_n \end{aligned}$$

$$\stackrel{(b)}{=} \frac{1}{n} \sum_{i=1}^n I(X_i; Y_{1,i}, S_{1,i} | Y_2^{i-1}, S_2^{i-1}, W_0, W_2) + \epsilon_n \quad (135)$$

$$= I(X_T; Y_{1,T}, S_{1,T} | Y_2^{T-1}, S_2^{T-1}, W_0, W_2, T) + \epsilon_n$$

$$\stackrel{(c)}{=} I(X; Y_1 | S_1, U) + \epsilon_n, \quad (136)$$

where we defined $Y_1 := Y_{1,T}$ and $S_1 := S_{1,T}$; and where (b) holds by the physically degradedness of the SDMBC which implies the Markov chain $(W_0, W_2, W_1, Y_1^{i-1}, S_1^{i-1}, Y_2^{i-1}, S_2^{i-1}) \rightarrow X_i \rightarrow (S_{1,i}, Y_{1,i}) \rightarrow (S_{2,i}, Y_{2,i})$, and (c) holds because $S_1 \sim P_{S_1}$ independent of (U, X) .

Recall that we assume the optimal estimators (51) in Lemma 3. Using the definitions of T , X , S_k above and defining $Z := Z_T$, we can write the average expected distortions as:

$$\frac{1}{n} \sum_{i=1}^n \mathbb{E}[d_k(S_{k,i}, \hat{s}_k^*(X_i, Z_i))] = \mathbb{E}[d_k(S_k, \hat{s}_k^*(X, Z))]. \quad (137)$$

Combining (134), (136), and (137) and letting $n \rightarrow \infty$, we obtain that there exists a limiting pmf P_{UX} such that the tuple $(U, X, S_1, S_2, Y_1, Y_2, Z) \sim P_{UX} P_{S_1 S_2} P_{Y_1 Y_2 Z | S_1 S_2 X}$ satisfies the rate-constraints

$$R_0 + R_2 \leq I(U; Y_2 | S_2) \quad (138)$$

$$R_1 \leq I(X; Y_1 | S_1, U) \quad (139)$$

and the distortion constraints

$$\mathbb{E}[d_k(S_k, \hat{s}_k^*(X, Z))] \leq D_k, \quad k = 1, 2, \quad (140)$$

This completes the proof.

APPENDIX E PROOF OF THEOREM 4

Fix a sequence (in n) of $(2^{nR_0}, 2^{nR_1}, 2^{nR_2}, n)$ codes satisfying (50). Fix then a blocklength n and consider an enhanced SDMBC where Receiver 1 observes the pair of states $\tilde{S}_1 = (S_1, S_2)$ and the pair of outputs $\tilde{Y}_1 = (Y_1, Y_2)$. The enhanced SDMBC is clearly physically degraded because for any input pmf P_X the Markov chain

$$X \text{---} (\tilde{S}_1, \tilde{Y}_1) \text{---} (S_2, Y_2) \quad (141)$$

holds.

Following the steps in the previous Appendix D, we can conclude that

$$R_0 + R_2 \leq I(U_2; Y_2 | S_2) + \epsilon_n \quad (142)$$

$$R_0 + R_1 + R_2 \leq I(X; Y_1, Y_2 | S_1, S_2) + \epsilon_n \quad (143)$$

and

$$\frac{1}{n} \sum_{i=1}^n \mathbb{E}[d_k(S_{k,i}, \hat{s}_k^*(X_i, Z_i))] = \mathbb{E}[d_k(S_k, \hat{s}_k^*(X, Z))], \quad k = 1, 2. \quad (144)$$

Consider next a reversely enhanced SDMBC where Receiver 1 observes only (Y_1, S_1) but Receiver 2 observes both state sequences $\tilde{S}_2 := (S_1, S_2)$ and both outputs $\tilde{Y}_2 := (Y_1, Y_2)$. Following again the steps in the previous Appendix D, but now with exchanged indices 1 and 2, we obtain:

$$R_0 + R_1 \leq I(U_1; Y_1 | S_1) + \epsilon_n \quad (145)$$

$$R_0 + R_1 + R_2 \leq I(X; Y_1, Y_2 | S_1, S_2) + \epsilon_n. \quad (146)$$

Combining all these inequalities and letting first $n \rightarrow \infty$ and then $\epsilon_n \downarrow 0$, establishes the desired converse result.

APPENDIX F
PROOFS FOR DUECK'S STATE-DEPENDENT BC

A. *Optimal Estimator of Lemma 3*

We first derive the optimal estimator $\hat{s}_k^*(x_1, x_2, y'_1, y'_2)$ of Lemma 3 for this example.

Case $y'_1 = y'_2 = 1$: In this case, $S_1 = S_2 = 1$ deterministically, and thus

$$\hat{s}_k^*(x_1, x_2, 1, 1) = 1, \quad \forall (x_1, x_2), \quad k = 1, 2. \quad (147)$$

Case $y_1 = 1'$ and $y'_2 = 0$: In this case, $S_1 = 1$ deterministically and

$$\hat{s}_1^*(x_1, x_2, 1, 0) = 1, \quad \forall (x_1, x_2). \quad (148)$$

To derive the optimal estimator for state S_2 , we notice that $y'_1 = 1$ implies $x_1 \oplus N = 1$, i.e., $N = x_1 \oplus 1$. As a consequence,

$$y'_2 = (x_2 \oplus x_1 \oplus 1)S_2. \quad (149)$$

So, for $x_2 = x_1$ we have $y'_2 = S_2 = 0$ and the optimal estimator sets

$$\hat{s}_2^*(x_1, x_2, 1, 0) = 0, \quad x_1 = x_2. \quad (150)$$

Instead for $x_2 \neq x_1$, the feedback output $y'_2 = 0$, irrespective of the state S_2 . The optimal estimator then is the constant estimator

$$\hat{s}_2^*(x_1, x_2, 1, 0) = \operatorname{argmax}_{\hat{s} \in \{0,1\}} P_S(\hat{s}), \quad x_1 \neq x_2. \quad (151)$$

Case $y'_1 = 1, y'_2 = 0$: Symmetric to the previous case $y'_1 = 0, y'_2 = 1$. The optimal estimators are as in (150) and (151), but with exchanged indices 1 and 2.

Case $y'_1 = y'_2 = 0$: To find the optimal estimators, we calculate the conditional probabilities $P_{S_k|X_1 X_2 Y'_1 Y'_2}(\cdot | x_1, x_2, y'_1, y'_2)$ for $y'_1 = y'_2 = 0$.

We again distinguish the two cases $x_1 = x_2$ and $x_1 \neq x_2$ and start by considering $x_1 = x_2$. In this case, $x_1 \oplus N = x_2 \oplus N$, and so if $S_k = 1$ then $y'_1 = y'_2 = 0$ only if $x_1 \oplus N = x_2 \oplus N = 0$, which happens with probability $1/2$ because N is Bernoulli- $1/2$. By the independence of the states and the inputs for $x_1 = x_2$ and $k = 1, 2$:

$$\begin{aligned} & P_{S_k|X_1 X_2 Y'_1 Y'_2}(1|x_1, x_2, 0, 0) \\ &= \frac{P_{S_k}(1)P_{Y'_1 Y'_2|X_1 X_2 S_k}(0, 0|x_1, x_2, 1)}{P_{Y'_1 Y'_2|X_1 X_2}(0, 0|x_1, x_2)} \\ &= \frac{P_S(1)1/2}{P_{Y'_1 Y'_2|X_1 X_2}(0, 0|x_1, x_2)}. \end{aligned} \quad (152a)$$

Let $\bar{k} := 3 - k$ for $k = 1, 2$. If $S_k = 0$, then $y'_1 = y'_2 = 0$ happens when either $x_1 \oplus N = x_2 \oplus N = 0$ or when $S_{\bar{k}} = 0$ and $x_1 \oplus N = x_2 \oplus N = 1$. Since these are exclusive events and have total probability of $1/2 + P_S(0)1/2$, we obtain for $x_1 = x_2$ and $k \in \{1, 2\}$:

$$\begin{aligned} & P_{S_k|X_1 X_2 Y'_1 Y'_2}(0|x_1, x_2, 0, 0) \\ &= \frac{P_{S_k}(0)P_{Y'_1 Y'_2|X_1 X_2 S_k}(0, 0|x_1, x_2, 0)}{P_{Y'_1 Y'_2|X_1 X_2}(0, 0|x_1, x_2)} \\ &= \frac{P_S(0)(1/2 + P_S(0)1/2)}{P_{Y'_1 Y'_2|X_1 X_2}(0, 0|x_1, x_2)}. \end{aligned} \quad (152b)$$

We conclude from (152) that for $y'_1 = y'_2 = 0$ and $x_1 = x_2$, the optimal estimators are

$$\hat{s}_k^*(x_1, x_2, 0, 0) = \mathbb{1} \{P_S(0)(1 + P_S(0)) < P_S(1)\}, \quad x_1 = x_2, \quad k = 1, 2. \quad (153)$$

We turn to the case $x_1 \neq x_2$, where $x_1 \oplus N = 1 \oplus (x_2 \oplus N)$. As before, if $S_k = 1$, then $Y'_k = 0$ only if $x_1 \oplus N = 0$, which happens with probability $1/2$. Now this implies $x_2 \oplus N = 1$, and thus $Y'_k = 0$ only if $S_k = 0$, which happens with probability $P_S(0)$. We thus obtain for $x_1 \neq x_2$ and $k = 1, 2$:

$$\begin{aligned} & P_{S_k|X_1X_2Y'_1Y'_2}(1|x_1, x_2, 0, 0) \\ &= \frac{P_{S_k}(1)P_{Y'_1Y'_2|X_1X_2S_k}(0, 0|x_1, x_2, 1)}{P_{Y'_1Y'_2|X_1X_2}(0, 0|x_1, x_2)} \\ &= \frac{P_S(1)P_S(0)1/2}{P_{Y'_1Y'_2|X_1X_2}(0, 0|x_1, x_2)}. \end{aligned} \quad (154a)$$

If $S_k = 0$, then $Y'_1 = Y'_2 = 0$ happens when $x_k \oplus N = 0$ or when $x_k \oplus N = 1$ and $S_k = 0$. Since these are exclusive events with total probability $1/2 + P_S(0)1/2$, we obtain for $x_1 \neq x_2$ and $k = 1, 2$:

$$\begin{aligned} & P_{S_k|X_1X_2Y'_1Y'_2}(0|x_1, x_2, 0, 0) \\ &= \frac{P_{S_k}(0)P_{Y'_1Y'_2|X_1X_2S_k}(0, 0|x_1, x_2, 0)}{P_{Y'_1Y'_2|X_1X_2}(0, 0|x_1, x_2)} \\ &= \frac{P_S(0)(1/2 + P_S(0)1/2)}{P_{Y'_1Y'_2|X_1X_2}(0, 0|x_1, x_2)}. \end{aligned} \quad (154b)$$

Since $P_S(1) < 1 + P_S(0)$, we conclude that for $y'_1 = 0, y'_2 = 0$ and $x_1 \neq x_2$, the optimal estimator is

$$\hat{s}_k^*(x_1, x_2, 0, 0) = 0, \quad x_1 \neq x_2, \quad k = 1, 2. \quad (155)$$

B. Minimum distortion

We evaluate the expected distortion of the optimal estimators in (92), for a given input pmf $P_{X_0X_1X_2}$. Let $t := \Pr[X_1 \neq X_2]$. We first consider the distortion on state S_2 :

$$\begin{aligned} & \mathbb{E}[d(S_2, \hat{s}_2^*(X_1, X_2, Y'_1, Y'_2))] \\ &= \sum_{(x_1, x_2, y'_1, y'_2) \in \{0,1\}^4} P_{X_1X_2Y'_1Y'_2}(x_1, x_2, y'_1, y'_2) \Pr[S_2 \neq \hat{s}_2^*(x_1, x_2, y'_1, y'_2) | X_1 = x_1, X_2 = x_2, Y'_1 = y'_1, Y'_2 = y'_2] \end{aligned} \quad (156)$$

$$\stackrel{(a)}{=} \sum_{(x_1, x_2, y'_1, y'_2) \in \{0,1\}^4} P_{X_1X_2Y'_1Y'_2}(x_1, x_2, y'_1, y'_2) \min_{\hat{s} \in \{0,1\}} P_{S_2|X_1X_2Y'_1Y'_2}(\hat{s} | x_1, x_2, y'_1, y'_2), \quad (157)$$

where (a) follows by the definition of the function \hat{s}_2^* .

In the previous Subsection F-A, we argued that for $y'_2 = 1$ or for $(y'_2 = 0, y'_1 = 1, x_1 = x_2)$, the state S_2 is deterministic ($S_2 = 1$ in the former case and $S_2 = 0$ in the latter) and thus $\min_{\hat{s} \in \{0,1\}} P_{S_2|X_1X_2Y'_1Y'_2}(\hat{s} | x_1, x_2, y'_1, y'_2) = 0$. We further argued that for $(y'_1 = 1, y'_2 = 0, x_1 \neq x_2)$ the transmitter learns nothing about state S_2 , which is thus still distributed according to P_S . Based on these observations, we continue from (157) as:

$$\begin{aligned} & \mathbb{E}[d(S_2, \hat{s}_2^*(X_1, X_2, Y'_1, Y'_2))] \\ &= \Pr[X_1 \neq X_2, Y'_1 = 1, Y'_2 = 0] \min\{P_S(0), P_S(1)\} \\ &\quad + \sum_{(x_1, x_2) \in \{0,1\}^2} P_{X_1X_2Y'_1Y'_2}(x_1, x_2, 0, 0) \min\{P_{S_1|X_1X_2Y'_1Y'_2}(0|x_1, x_2, 0, 0), P_{S_1|X_1X_2Y'_1Y'_2}(1|x_1, x_2, 0, 0)\} \\ &\stackrel{(b)}{=} \Pr[X_1 \neq X_2, N = X_1 \oplus 1, S_1 = 1] \min\{P_S(0), P_S(1)\} \\ &\quad + \Pr[X_1 = X_2] \frac{1}{2} \min\{P_S(1), P_S(0)(1 + P_S(0))\} \\ &\quad + \Pr[X_1 \neq X_2] \frac{1}{2} P_S(0)P_S(1) \end{aligned} \quad (158)$$

$$= \frac{1}{2}tq(\min\{q, (1-q)\} + (1-q)) + \frac{1}{2}(1-t)q \min\{q, (1-q)(2-q)\}. \quad (159)$$

where in (b) we used (152)–(155) and the fact that when $X_1 \neq X_2$, then event $\{Y'_1 = 1, Y'_2 = 0\}$ is equivalent to event $\{N = X_1 \oplus 1, S_1 = 1\}$.

C. Proof of the Outer Bound

The outer bound is based on Theorem 4, as detailed out in the following. The single-rate constraints (75a) specialize to

$$R_k \leq I(U_k; Y'_k, X_0 | S_1, S_2) \quad (160)$$

$$\stackrel{(c)}{=} I(U_k; X_0) \quad (161)$$

$$\leq 1, \quad (162)$$

where the equality holds by the chain rule, because (U_1, X_0) and (S_1, S_2) are independent, and because $I(U_1; Y'_1 | X_0, S_1, S_2) = 0$ due to the Bernoulli-1/2 noise N .

Defining $t := \Pr[X_1 \neq X_2]$, Bound (75b) specializes to:

$$R_1 + R_2 \leq I(X_0, X_1, X_2; Y'_1, Y'_2, X_0 | S_1, S_2) \quad (163)$$

$$\stackrel{(d)}{=} H(X_0) + I(X_1, X_2; Y'_2 | S_1, S_2, Y'_1, X_0) \quad (164)$$

$$\stackrel{(e)}{=} H(X_0) + I(X_1, X_2; Y'_2 | S_1 = 1, S_2 = 1, Y'_1, X_0) \quad (165)$$

$$= H(X_0) + I(X_1, X_2; Y'_2 \oplus Y'_1 | S_1 = 1, S_2 = 1, X_0) \quad (166)$$

$$\stackrel{(f)}{\leq} H(X_0) + P_{S_1, S_2}(1, 1)H(X_1 \oplus X_2) \quad (167)$$

$$\leq 1 + q^2 H_b(t). \quad (168)$$

where (d) holds by the chain rule and because $I(X_1, X_2; Y'_1 | X_0, S_1, S_2) = 0$ due to the Bernoulli-1/2 noise N ; (e) holds because for $(s_1, s_2) \neq (1, 1)$ the mutual information term $I(X_1, X_2; Y'_2 | S_1 = s_1, S_2 = s_2, Y'_1, X_0) = 0$ due to the Bernoulli-1/2 noise N ; and (f) holds because for $S_1 = S_2 = 1$ we have $Y'_2 \oplus Y'_1 = (X_2 \oplus N) \oplus (X_1 \oplus N) = X_2 \oplus X_1$ and because conditioning can only reduce entropy.

The sum-rate constraint (168) is maximized for $t = 1/2$, which combined with (162) establishes the converse to the capacity region in (97).

D. Proof of Achievability Results

We evaluate Proposition 1 for different choices of the involved random variables. Since we ignore the common rate R_0 , bound (77d) is not active and can be ignored.

1) *First choice:*

- X_0, X_1, X_2 Bernoulli-1/2 with X_0 independent of (X_1, X_2) and $X_1 = X_2 = x$ with probability $\frac{1-t}{2}$ for all $x \in \{0, 1\}$;
- $U_k = X_k$, for $k = 0, 1, 2$;
- $V_1 = (X_0, X_1)$, $V_2 = (X_0, X_2)$, $V_0 = X_1 \oplus Y'_1$.

We plug this choice into Proposition 1. Constraint (77a) evaluates to:

$$R_1 \leq I(U_0, U_1; Y_1, V_1 | S_1) - I(U_0, U_1, U_2, Z; V_0, V_1 | S_1, Y_1) \quad (169)$$

$$= I(X_0, X_1; X_0, Y'_1, S_1, S_2, X_1 | S_1) - I(X_0, X_1, X_2, Y'_1, Y'_2; X_1 \oplus Y'_1, X_0, X_1 | S_1, S_2, X_0, Y'_1) \quad (170)$$

$$\stackrel{(e)}{=} H(X_0) + H(X_1) - H(X_1 | Y'_1) \quad (171)$$

$$= H(X_0) = 1 \quad (172)$$

where (e) holds because Y'_1 is independent of X_1 due to the Bernoulli-1/2 noise N .

Constraint (77b) evaluates to:

$$R_2 \leq I(U_0, U_2; Y_2, V_2 | S_2) - I(U_0, U_1, U_2, Z; V_0, V_2 | S_2, Y_2) \quad (173)$$

$$= I(X_0, X_2; X_0, Y'_2, S_1, S_2, X_2 | S_1) - I(X_0, X_1, X_2, Y'_1, Y'_2; X_1 \oplus Y'_1, X_0, X_2 | S_1, S_2, X_0, Y'_2) \quad (174)$$

$$\stackrel{(f)}{=} H(X_0) + H(X_2) - H(X_2) - H(X_1 \oplus Y'_1 | S_1, S_2, X_0, Y'_2, X_2) \quad (175)$$

$$\stackrel{(g)}{=} 1 - (1 - q)(H_b(t) + q), \quad (176)$$

where (f) holds because of the chain rule and the independence of X_2 and Y_2' ; and (g) holds because for $S_1 = 0$ the XOR $X_1 \oplus Y_1' = X_1$ and thus $H(X_1 \oplus Y_1' | S_1, S_2, X_0, Y_2', X_2) = H(X_1 | X_2)$, for $S_1 = S_2 = 1$ the XOR $X_1 \oplus Y_1' = X_2 \oplus Y_2'$, and finally for $S_1 = 1$ and $S_2 = 0$ the XOR $X_1 \oplus Y_1' = N$ independent of $(Y_2' = 0, X_2)$.

Constraint (77b) evaluates to:

$$\begin{aligned} R_1 + R_2 &\leq I(U_1; Y_1, V_1 | U_0, S_1) + I(U_2; Y_2, V_2 | U_0, S_2) + \min_{k \in \{1,2\}} I(U_0; Y_k, V_k | S_k) - I(U_1; U_2 | U_0) \\ &\quad - I(U_0, U_1, U_2, Z; V_1 | V_0, S_1, Y_1) - I(U_0, U_1, U_2, Z; V_2 | V_0, S_2, Y_2) \\ &\quad - \max_{k \in \{1,2\}} I(U_0, U_1, U_2, Z; V_0 | S_k, Y_k) \end{aligned} \quad (177)$$

$$\begin{aligned} &= \underbrace{I(X_1; X_0, Y_1', S_1, S_2, X_1 | X_0, S_1)}_{=H(X_1)} + \underbrace{I(X_2; X_0, Y_2', S_1, S_2, X_2 | X_0, S_2)}_{=H(X_2)} \\ &\quad + \min_{k \in \{1,2\}} \underbrace{I(X_0; X_0, Y_k', S_1, S_2, X_k | S_k)}_{=H(X_0)} - \underbrace{I(X_1; X_2)}_{=H(X_1) - H(X_1|X_2)} \\ &\quad - \underbrace{I(X_0, X_1, X_2, Y_1', Y_2'; X_0, X_1 | X_1 \oplus Y_1', X_0, S_1, S_2, Y_1')}_{=0} \\ &\quad - \underbrace{I(X_0, X_1, X_2, Y_1', Y_2'; X_0, X_2 | X_1 \oplus Y_1', X_0, S_1, S_2, Y_2')}_{=H(X_2|X_1 \oplus Y_1', S_1, S_2, Y_2')} \\ &\quad - \max_{k \in \{1,2\}} \underbrace{I(X_0, X_1, X_2, Y_1', Y_2'; X_1 \oplus Y_1' | S_1, S_2, X_0, Y_k')}_{=H(X_1 \oplus Y_1' | S_1, S_2, Y_k')} \end{aligned} \quad (178)$$

$$\stackrel{(h)}{=} 2 + H_b(t) - H(X_2 | X_1 \oplus Y_1', S_1, S_2, Y_2') - H(X_1 \oplus Y_1') \quad (179)$$

$$\stackrel{(i)}{=} 1 + H_b(t) - (1 - q)H_b(t) - q(1 - q), \quad (180)$$

where (h) holds because $X_1 \oplus Y_1'$ is independent of (S_1, S_2, Y_k') , for $k = 1, 2$; and (i) holds because for $S_1 = S_2 = 1$ we have $X_2 = Y_2' \oplus Y_1' \oplus X_1$ and thus $H(X_2 | X_1 \oplus Y_1', S_1 = 1, S_2 = 1, Y_2') = 0$, for $S_1 = 0$ the XOR $X_1 \oplus Y_1' = X_1$ and thus $H(X_2 | X_1 \oplus Y_1', S_1 = 1, S_2, Y_2') = H(X_2 | X_1) = H_b(t)$, and finally for $S_1 = 1$ and $S_2 = 0$, we have $X_1 \oplus Y_1' = N$ and $Y_2' = 0$ and thus $H(X_2 | X_1 \oplus Y_1', S_1 = 1, S_2 = 0, Y_2') = H(X_2) = 1$.

The presented choice of parameters can thus achieve all rate-distortion tuples $(R_0, R_1, R_2, D_1, D_2)$ satisfying the distortion constraints in (94) (which only depends on the probability $t := \Pr[X_1 \neq X_2]$) and

$$R_1 \leq 1 \quad (181a)$$

$$R_2 \leq 1 - (1 - q)(H_b(t) + q) \quad (181b)$$

$$R_1 + R_2 \leq 1 + qH_b(t) - q(1 - q). \quad (181c)$$

2) *Second choice*: Same as the first choice except that $V_0 = X_2 \oplus Y_2'$. Following symmetric arguments as above, we conclude that for this choice the constraints in (77) evaluate to:

$$R_1 \leq 1 - (1 - q)(H_b(t) + q) \quad (182a)$$

$$R_2 \leq 1 \quad (182b)$$

$$R_1 + R_2 \leq 1 + qH_b(t) - q(1 - q). \quad (182c)$$

3) *Combining the Choices and Time-Sharing*: From the two previous subsections, we conclude that for any $t \in [0, 1]$ the set of rate-distortion tuples $(R_0, R_1, R_2, D_1, D_2)$ is achievable if it satisfies (94) and

$$R_0 + R_1 \leq 1 \quad (183a)$$

$$R_0 + R_2 \leq 1 \quad (183b)$$

$$R_0 + R_1 + R_2 \leq 1 + qH_b(t) - q(1 - q). \quad (183c)$$

As previously discussed, for $q \leq 1/2$, the distortion constraints (94) do not depend on t , and thus without loss in optimality in (183) one can set $t = 1/2$, which results in a sum-rate constraint

$$R_0 + R_1 + R_2 \leq 1 + q^2. \quad (184)$$

Combined with (183a) and (183b), this sum-rate bound establishes the achievability of the capacity region in (97).

For $q > 1/2$ the distortion constraints (94) are either increasing or decreasing in t . The set of achievable rate-distortion tuples is then obtained by varying t either over $[0, 1/2]$ or over $[1/2, 1]$. Numerical results indicate that the so obtained set is not convex and the convex hull is obtained by considering convex combinations between different values of $t > 0$ and $t = 0$ for $q \in [2/3, 1]$ and $t = 1$ for $q \in [1/2, 2/3]$.
